

Study Guide: Vibration ODEs

Hans Petter Langtangen^{1,2}

Center for Biomedical Computing, Simula Research Laboratory¹

Department of Informatics, University of Oslo²

Sep 6, 2013

A simple vibration problem

$$u'' + \omega^2 u = 0, \quad u(0) = I, \quad u'(0) = 0, \quad t \in (0, T]. \quad (1)$$

Exact solution:

$$u(t) = I \cos(\omega t). \quad (2)$$

$u(t)$ oscillates with constant amplitude I and (angular) frequency ω . Period: $P = 2\pi/\omega$.

A centered finite difference scheme; step 1 and 2

- Strategy: follow the four steps of the finite difference method.
- Step 1: Introduce a time mesh, here uniform on $[0, T]$:
 $t_n = n\Delta t$
- Step 2: Let the ODE be satisfied at each mesh point:

$$u''(t_n) + \omega^2 u(t_n) = 0, \quad n = 1, \dots, N_t. \quad (3)$$

A centered finite difference scheme; step 3

Step 3: Approximate derivative(s) by finite difference approximation(s). Very common (standard!) formula for u'' :

$$u''(t_n) \approx \frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2}. \quad (4)$$

Use this discrete initial condition together with the ODE at $t = 0$ to eliminate u^{-1} (insert (4) in (3)):

$$\frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2} = -\omega^2 u^n. \quad (5)$$

A centered finite difference scheme; step 4

Step 4: Formulate the computational algorithm. Assume u^{n-1} and u^n are known, solve for unknown u^{n+1} :

$$u^{n+1} = 2u^n - u^{n-1} - \omega^2 u^n. \quad (6)$$

Nick names for this scheme: Stormer's method or Verlet integration.

Computing the first step

- The formula breaks down for u^1 because u^{-1} is unknown and outside the mesh!
- And: we have not used the initial condition $u'(0) = 0$.

Discretize $u'(0) = 0$ by a centered difference

$$\frac{u^1 - u^{-1}}{2\Delta t} = 0 \quad \Rightarrow \quad u^{-1} = u^1. \quad (7)$$

Inserted in (6) for $n = 0$ gives

$$u^1 = u^0 - \frac{1}{2}\Delta t^2 \omega^2 u^0. \quad (8)$$

The computational algorithm

- ❶ $u^0 = I$
- ❷ compute u^1 from (8)
- ❸ for $n = 1, 2, \dots, N_t - 1$:
 - ❶ compute u^{n+1} from (6)

More precisely expressed in Python:

```
t = linspace(0, T, Nt+1)  # mesh points in time
dt = t[1] - t[0]          # constant time step.
u = zeros(Nt+1)           # solution

u[0] = I
u[1] = u[0] - 0.5*dt**2*w**2*u[0]
for n in range(1, Nt):
    u[n+1] = 2*u[n] - u[n-1] - dt**2*w**2*u[n]
```

Note: w is consistently used for ω in code.

With $[D_t D_t u]^n$ as the finite difference approximation to $u''(t_n)$ we can write

$$[D_t D_t u + \omega^2 u = 0]^n. \quad (9)$$

$[D_t D_t u]^n$ means applying a central difference with step $\Delta t/2$ twice:

$$[D_t(D_t u)]^n = \frac{[D_t u]^{n+1/2} - [D_t u]^{n-1/2}}{\Delta t}$$

which is written out as

$$\frac{1}{\Delta t} \left(\frac{u^{n+1} - u^n}{\Delta t} - \frac{u^n - u^{n-1}}{\Delta t} \right) = \frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2}.$$

$$[u = I]^0, \quad [D_{2t}u = 0]^0, \quad (10)$$

where $[D_{2t}u]^n$ is defined as

$$[D_{2t}u]^n = \frac{u^{n+1} - u^{n-1}}{2\Delta t}. \quad (11)$$

u is often displacement/position, u' is velocity and can be computed by

$$u'(t_n) \approx \frac{u^{n+1} - u^{n-1}}{2\Delta t} = [D_{2t}u]^n. \quad (12)$$

Core algorithm

```
from numpy import *
from matplotlib.pyplot import *

def solver(I, w, dt, T):
    """
    Solve  $u'' + w^2 u = 0$  for  $t$  in  $(0, T]$ ,  $u(0)=I$  and  $u'(0)=0$ ,
    by a central finite difference method with time step  $dt$ .
    """
    dt = float(dt)
    Nt = int(round(T/dt))
    u = zeros(Nt+1)
    t = linspace(0, Nt*dt, Nt+1)

    u[0] = I
    u[1] = u[0] - 0.5*dt**2*w**2*u[0]
    for n in range(1, Nt):
        u[n+1] = 2*u[n] - u[n-1] - dt**2*w**2*u[n]
    return u, t
```

Plotting

```
def exact_solution(t, I, w):  
    return I*cos(w*t)  
  
def visualize(u, t, I, w):  
    plot(t, u, 'r--o')  
    t_fine = linspace(0, t[-1], 1001) # very fine mesh for u_e  
    u_e = exact_solution(t_fine, I, w)  
    hold('on')  
    plot(t_fine, u_e, 'b-')  
    legend(['numerical', 'exact'], loc='upper left')  
    xlabel('t')  
    ylabel('u')  
    dt = t[1] - t[0]  
    title('dt=%g' % dt)  
    umin = 1.2*u.min(); umax = -umin  
    axis([t[0], t[-1], umin, umax])  
    savefig('vib1.png')  
    savefig('vib1.pdf')  
    savefig('vib1.eps')
```

Main program

```
I = 1
w = 2*pi
dt = 0.05
num_periods = 5
P = 2*pi/w      # one period
T = P*num_periods
u, t = solver(I, w, dt, T)
visualize(u, t, I, w, dt)
```

User interface: command line

```
import argparse
parser = argparse.ArgumentParser()
parser.add_argument('--I', type=float, default=1.0)
parser.add_argument('--w', type=float, default=2*pi)
parser.add_argument('--dt', type=float, default=0.05)
parser.add_argument('--num_periods', type=int, default=5)
a = parser.parse_args()
I, w, dt, num_periods = a.I, a.w, a.dt, a.num_periods
```

Running the program

vib_undamped.py:

```
Terminal> python vib_undamped.py --dt 0.05 --num_periods 40
```

Generates frames tmp_vib%04d.png in files. Can make movie:

```
Terminal> avconv -r 12 -i tmp_vib%04d.png -vcodec flv movie.flv
```

Can use ffmpeg instead of avconv.

<i>Format</i>	<i>Codec and filename</i>
<i>Flash</i>	<i>-vcodec flv movie.flv</i>
<i>MP4</i>	<i>-vcodec libx64 movie.mp4</i>
<i>Webm</i>	<i>-vcodec libvpx movie.webm</i>
<i>Ogg</i>	<i>-vcodec libtheora movie.ogg</i>

First steps for testing and debugging

- **Testing very simple solutions:** $u = \text{const}$ or $u = ct + d$ do not apply here (without a force term in the equation: $u'' + \omega^2 u = f$).
- **Hand calculations:** calculate u^1 and u^2 and compare with program.

Checking convergence rates

The next function estimates convergence rates, i.e., it

- performs m simulations with halved time steps: $2^{-k}\Delta t$, $k = 0, \dots, m - 1$,
- computes the L_2 norm of the error,
$$E = \sqrt{\Delta t_i \sum_{n=0}^{N_t-1} (u^n - u_e(t_n))^2}$$
 in each case,
- estimates the rates r_i from two consecutive experiments $(\Delta t_{i-1}, E_{i-1})$ and $(\Delta t_i, E_i)$, assuming $E_i = C\Delta t_i^{r_i}$ and $E_{i-1} = C\Delta t_{i-1}^{r_i}$:

Implementational details

```
def convergence_rates(m, num_periods=8):  
    """  
    Return m-1 empirical estimates of the convergence rate  
    based on m simulations, where the time step is halved  
    for each simulation.  
    """  
    w = 0.35; I = 0.3  
    dt = 2*pi/w/30 # 30 time step per period 2*pi/w  
    T = 2*pi/w*num_periods  
    dt_values = []  
    E_values = []  
    for i in range(m):  
        u, t = solver(I, w, dt, T)  
        u_e = exact_solution(t, I, w)  
        E = sqrt(dt*sum((u_e-u)**2))  
        dt_values.append(dt)  
        E_values.append(E)  
        dt = dt/2  
  
    r = [log(E_values[i-1]/E_values[i])/  
        log(dt_values[i-1]/dt_values[i])  
        for i in range(1, m, 1)]  
    return r
```

Result: r contains values equal to 2.00 - as expected!

Nose test

Use final `r[-1]` in a unit test:

```
def test_convergence_rates():  
    r = convergence_rates(m=5, num_periods=8)  
    # Accept rate to 1 decimal place  
    nt.assert_almost_equal(r[-1], 2.0, places=1)
```

Complete code in `vib_undamped.py`.

Long time simulations

Effect of the time step on long simulations

- The numerical solution seems to have right amplitude.
- There is a phase error (reduced by reducing the time step).
- The total phase error seems to grow with time.

Using a moving plot window

- In long time simulations we need a plot window that follows the solution.
- Method 1: `scitools.MovingPlotWindow`.
- Method 2: `scitools.avplotter` (ASCII vertical plotter).

Example:

```
Terminal> python vib_undamped.py --dt 0.05 --num_periods 40
```

Movie of the moving plot window.

Analysis of the numerical scheme

Deriving an exact numerical solution; ideas

- Linear, homogeneous, difference equation for u^n .
- Has solutions $u^n \sim A^n$, where A is unknown (number).
- Here: $u_e(t) = I \cos(\omega t) \sim I \exp(i\omega t) = I(e^{i\omega\Delta t})^n$
- Trick for simplifying the algebra: $u^n = A^n$, with $A = \exp(i\tilde{\omega}\Delta t)$, then find $\tilde{\omega}$
- $\tilde{\omega}$: unknown *numerical frequency* (easier to calculate than A)
- $\omega - \tilde{\omega}$ is the *phase error*
- Use the real part as the physical relevant part of a complex expression

Deriving an exact numerical solution; calculations (1)

$$u^n = A^n = \exp(\tilde{\omega} \Delta t n) = \exp(\tilde{\omega} t) = \cos(\tilde{\omega} t) + i \sin(\tilde{\omega} t).$$

$$\begin{aligned} [D_t D_t u]^n &= \frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2} \\ &= I \frac{A^{n+1} - 2A^n + A^{n-1}}{\Delta t^2} \\ &= I \frac{\exp(i\tilde{\omega}(t + \Delta t)) - 2\exp(i\tilde{\omega}t) + \exp(i\tilde{\omega}(t - \Delta t))}{\Delta t^2} \\ &= I \exp(i\tilde{\omega}t) \frac{1}{\Delta t^2} (\exp(i\tilde{\omega}(\Delta t)) + \exp(i\tilde{\omega}(-\Delta t)) - 2) \\ &= I \exp(i\tilde{\omega}t) \frac{2}{\Delta t^2} (\cosh(i\tilde{\omega}\Delta t) - 1) \\ &= I \exp(i\tilde{\omega}t) \frac{2}{\Delta t^2} (\cos(\tilde{\omega}\Delta t) - 1) \\ &= -I \exp(i\tilde{\omega}t) \frac{4}{\Delta t^2} \sin^2\left(\frac{\tilde{\omega}\Delta t}{2}\right) \end{aligned}$$

Deriving an exact numerical; calculations (2)

The scheme (6) with $u^n = I \exp(i\omega \tilde{\Delta} t n)$ inserted gives

$$-I \exp(i\tilde{\omega} t) \frac{4}{\Delta t^2} \sin^2\left(\frac{\tilde{\omega} \Delta t}{2}\right) + \omega^2 I \exp(i\tilde{\omega} t) = 0, \quad (13)$$

which after dividing by $I \exp(i\tilde{\omega} t)$ results in

$$\frac{4}{\Delta t^2} \sin^2\left(\frac{\tilde{\omega} \Delta t}{2}\right) = \omega^2. \quad (14)$$

Solve for $\tilde{\omega}$:

$$\tilde{\omega} = \pm \frac{2}{\Delta t} \sin^{-1}\left(\frac{\omega \Delta t}{2}\right). \quad (15)$$

- Phase error because $\tilde{\omega} \neq \omega$.
- But how good is the approximation $\tilde{\omega}$ to ω ?

Polynomial approximation of the phase error

Taylor series expansion for small Δt gives a formula that is easier to understand:

```
>>> from sympy import *
>>> dt, w = symbols('dt w')
>>> w_tilde = asin(w*dt/2).series(dt, 0, 4)*2/dt
>>> print w_tilde
(dt*w + dt**3*w**3/24 + O(dt**4))/dt # observe final /dt
```

$$\tilde{\omega} = \omega \left(1 + \frac{1}{24} \omega^2 \Delta t^2 \right) + \mathcal{O}(\Delta t^3). \quad (16)$$

The numerical frequency is too large (to fast oscillations).

Plot of the phase error

Recommendation: 25-30 points per period.

$$u^n = l \cos(\tilde{\omega} n \Delta t), \quad \tilde{\omega} = \frac{2}{\Delta t} \sin^{-1} \left(\frac{\omega \Delta t}{2} \right). \quad (17)$$

The error mesh function,

$$e^n = u_e(t_n) - u^n = l \cos(\omega n \Delta t) - l \cos(\tilde{\omega} n \Delta t)$$

is ideal for verification and analysis.

Convergence of the numerical scheme

Can easily show *convergence*:

$$e^n \rightarrow 0 \text{ as } \Delta t \rightarrow 0,$$

because

$$\lim_{\Delta t \rightarrow 0} \tilde{\omega} = \lim_{\Delta t \rightarrow 0} \frac{2}{\Delta t} \sin^{-1} \left(\frac{\omega \Delta t}{2} \right) = \omega,$$

by L'Hopital's rule or simply asking

`(2/x)*asin(w*x/2) as x->0` in WolframAlpha.

Observations:

- Numerical solution has constant amplitude (desired!), but phase error.
- Constant amplitude requires $\sin^{-1}(\omega\Delta t/2)$ to be real-valued $\Rightarrow |\omega\Delta t/2| \leq 1$.
- $\sin^{-1}(x)$ is complex if $|x| > 1$, and then $\tilde{\omega}$ becomes complex.

What is the consequence of complex $\tilde{\omega}$?

- Set $\tilde{\omega} = \tilde{\omega}_r + i\tilde{\omega}_i$.
- Since $\sin^{-1}(x)$ has a negative* imaginary part for $x > 1$, $\exp(i\omega\tilde{t}) = \exp(-\tilde{\omega}_i t) \exp(i\tilde{\omega}_r t)$ leads to exponential growth $e^{-\tilde{\omega}_i t}$ when $-\tilde{\omega}_i t > 0$.
- This is *instability* because the qualitative behavior is wrong.

The stability criterion

Cannot tolerate growth and must therefore demand a *stability criterion*

$$\frac{\omega \Delta t}{2} \leq 1 \quad \Rightarrow \quad \Delta t \leq \frac{2}{\omega}. \quad (18)$$

Try $\Delta t = \frac{2}{\omega} + 9.01 \cdot 10^{-5}$:

Summary of the analysis

We can draw three important conclusions:

- ➊ The key parameter in the formulas is $p = \omega \Delta t$.
 - ➊ Period of oscillations: $P = 2\pi/\omega$
 - ➋ Number of time steps per period: $N_P = P/\Delta t$
 - ➌ $\Rightarrow p = \omega \Delta t = 2\pi/N_P \sim 1/N_P$
 - ➍ The smallest possible N_P is 2 $\Rightarrow p \in (0, \pi]$
- ➋ For $p \leq 2$ the amplitude of u^n is constant (stable solution)
- ➌ u^n has a relative phase error $\tilde{\omega}/\omega \approx 1 + \frac{1}{24}p^2$, making numerical peaks occur too early

Alternative schemes based on 1st-order equations

Rewriting 2nd-order ODE as system of two 1st-order ODEs

The vast collection of ODE solvers (e.g., in Odespy) cannot be applied to

$$u'' + \omega^2 u = 0$$

unless we write this higher-order ODE as a system of 1st-order ODEs.

Introduce an auxiliary variable $v = u'$:

$$u' = v, \tag{19}$$

$$v' = -\omega^2 u. \tag{20}$$

Initial conditions: $u(0) = I$ and $v(0) = 0$.

The Forward Euler scheme

We apply the Forward Euler scheme to each component equation:

$$\begin{aligned} [D_t^+ u &= v]^n, \\ [D_t^+ v &= -\omega^2 u]^n, \end{aligned}$$

or written out,

$$u^{n+1} = u^n + \Delta t v^n, \tag{21}$$

$$v^{n+1} = v^n - \Delta t \omega^2 u^n. \tag{22}$$

The Backward Euler scheme

We apply the Backward Euler scheme to each component equation:

$$[D_t^- u = v]^{n+1}, \quad (23)$$

$$[D_t^- v = -\omega u]^{n+1}. \quad (24)$$

Written out:

$$u^{n+1} - \Delta t v^{n+1} = u^n, \quad (25)$$

$$v^{n+1} + \Delta t \omega^2 u^{n+1} = v^n. \quad (26)$$

This is a *coupled* 2×2 system for the new values at $t = t_{n+1}$!

The Crank-Nicolson scheme

$$[D_t u = \bar{v}^t]^{n+\frac{1}{2}}, \quad (27)$$

$$[D_t v = -\omega \bar{u}^t]^{n+\frac{1}{2}}. \quad (28)$$

The result is also a coupled system:

$$u^{n+1} - \frac{1}{2}\Delta t v^{n+1} = u^n + \frac{1}{2}\Delta t v^n, \quad (29)$$

$$v^{n+1} + \frac{1}{2}\Delta t \omega^2 u^{n+1} = v^n - \frac{1}{2}\Delta t \omega^2 u^n. \quad (30)$$

Comparison of schemes via Odespy

Can use Odespy to compare many methods for first-order schemes:

```
import odespy
import numpy as np

def f(u, t, w=1):
    u, v = u # u is array of length 2 holding our [u, v]
    return [v, -w**2*u]

def run_solvers_and_plot(solvers, timesteps_per_period=20,
                        num_periods=1, I=1, w=2*np.pi):
    P = 2*np.pi/w # one period
    dt = P/timesteps_per_period
    Nt = num_periods*timesteps_per_period
    T = Nt*dt
    t_mesh = np.linspace(0, T, Nt+1)

    legends = []
    for solver in solvers:
        solver.set(f_kwargs={'w': w})
        solver.set_initial_condition([I, 0])
        u, t = solver.solve(t_mesh)
```

Forward and Backward Euler and Crank-Nicolson

```
solvers = [  
    odespy.ForwardEuler(f),  
    # Implicit methods must use Newton solver to converge  
    odespy.BackwardEuler(f, nonlinear_solver='Newton'),  
    odespy.CrankNicolson(f, nonlinear_solver='Newton'),  
]
```

Two plot types:

- $u(t)$ vs t
- Parameterized curve $(u(t), v(t))$ in *phase space*
- Exact curve is an ellipse: $(I \cos \omega t, -\omega I \sin \omega t)$, closed and periodic

Phase plane plot of the numerical solutions

Note: CrankNicolson in Odespy leads to the name MidpointImplicit.

Plain solution curves

Figure: Comparison of classical schemes.

Observations from the figures

- Forward Euler has growing amplitude and outward (u, v) spiral - pumps energy into the system.
- Backward Euler is opposite: decreasing amplitude, inward spiral, extracts energy.
- **Forward and Backward Euler are useless for vibrations.**
- Crank-Nicolson (MidpointImplicit) looks much better.

Runge-Kutta methods of order 2 and 4; short time series

Runge-Kutta methods of order 2 and 4; longer time series

Crank-Nicolson; longer time series

Observations of RK and CN methods

- 4th-order Runge-Kutta is very accurate, also for large Δt .
- 2th-order Runge-Kutta is almost as bad as Forward and Backward Euler.
- Crank-Nicolson is accurate, but the amplitude is not as accurate as the difference scheme for $u'' + \omega^2 u = 0$.

The Euler-Cromer method; idea

Forward-backward discretization of the 2x2 system:

- Update u with Forward Euler
- Update v with Backward Euler, using latest u

$$[D_t^+ u = v]^n, \quad (31)$$

$$[D_t^- v = -\omega u]^{n+1}. \quad (32)$$

The Euler-Cromer method; complete formulas

Written out:

$$u^0 = I, \quad (33)$$

$$v^0 = 0, \quad (34)$$

$$u^{n+1} = u^n + \Delta t v^n, \quad (35)$$

$$v^{n+1} = v^n - \Delta t \omega^2 u^{n+1}. \quad (36)$$

Names: Forward-backward scheme, Semi-implicit Euler method, symplectic Euler, semi-explicit Euler, Newton-Stormer-Verlet, and Euler-Cromer.

Forward Euler and Backward Euler are both $\mathcal{O}(\Delta t)$ approximations. What about the overall scheme? Expect $\mathcal{O}(\Delta t)$...

Equivalence with the scheme for the second-order ODE

Goal: eliminate v^n . We have

$$v^n = v^{n-1} - \Delta t \omega^2 u^n,$$

which can be inserted in (35) to yield

$$u^{n+1} = u^n + \Delta t v^{n-1} - \Delta t^2 \omega^2 u^n. \quad (37)$$

Using (35),

$$v^{n-1} = \frac{u^n - u^{n-1}}{\Delta t},$$

and when this is inserted in (37) we get

$$u^{n+1} = 2u^n - u^{n-1} - \Delta t^2 \omega^2 u^n \quad (38)$$

Comparison of the treatment of initial conditions

- The Euler-Cromer scheme is nothing but the centered scheme for $u'' + \omega^2 u = 0$ (6)!
- The previous analysis of this scheme then also applies to the Euler-Cromer method!
- What about the initial conditions?

$$u' = v = 0 \quad \Rightarrow \quad v^0 = 0,$$

and (35) implies $u^1 = u^0$, while (36) says $v^1 = -\omega^2 u^0$.

This $u^1 = u^0$ approximation corresponds to a first-order Forward Euler discretization of $u'(0) = 0$: $[D_t^+ u = 0]^0$.

A method utilizing a staggered mesh

- The Euler-Cromer scheme uses two unsymmetric differences in a symmetric way...
- We can derive the method from a more pedagogical point of view where we use a *staggered mesh* and only centered differences

Staggered mesh:

- u is unknown at mesh points $t_0, t_1, \dots, t_n, \dots$
- v is unknown at mesh points $t_{1/2}, t_{3/2}, \dots, t_{n+1/2}, \dots$
(between the u points)

Centered differences on a staggered mesh

$$[D_t u = v]^{n+\frac{1}{2}}, \quad (39)$$

$$[D_t v = -\omega u]^{n+1}. \quad (40)$$

Written out:

$$u^{n+1} = u^n + \Delta t v^{n+\frac{1}{2}}, \quad (41)$$

$$v^{n+\frac{3}{2}} = v^{n+\frac{1}{2}} - \Delta t \omega^2 u^{n+1}. \quad (42)$$

or shift one time level back (purely of esthetic reasons):

$$u^n = u^{n-1} + \Delta t v^{n-\frac{1}{2}}, \quad (43)$$

$$v^{n+\frac{1}{2}} = v^{n-\frac{1}{2}} - \Delta t \omega^2 u^n. \quad (44)$$

Comparison with the scheme for the 2nd-order ODE

- Can eliminate $v^{n\pm 1/2}$ and get the centered scheme for $u'' + \omega^2 u = 0$
- What about the initial conditions? Their equivalent too!

$u(0) = 0$ and $u'(0) = v(0) = 0$ give $u^0 = I$ and

$$v(0) \approx \frac{1}{2}(v^{-\frac{1}{2}} + v^{\frac{1}{2}}) = 0, \quad \Rightarrow \quad v^{-\frac{1}{2}} = -v^{\frac{1}{2}}.$$

Combined with the scheme on the staggered mesh we get

$$u^1 = u^0 - \frac{1}{2}\Delta t^2 \omega^2 I,$$

Generalization: damping, nonlinear spring, and external excitation

$$mu'' + f(u') + s(u) = F(t), \quad u(0) = I, \quad u'(0) = V, \quad t \in (0, T]. \quad (45)$$

Input data: m , $f(u')$, $s(u)$, $F(t)$, I , V , and T .

Typical choices of f and s :

A centered scheme for quadratic damping

- $f(u') = bu'|u'|$ leads to a quadratic equation for u^{n+1}
- Instead of solving the quadratic equation, we use a geometric mean approximation

$$[mD_t D_t u + bu'|u'| + s(u) = F]^n, \quad (52)$$

Compute $u'|u'|$ by a *geometric mean*!

Using a geometric mean to linearize the equation

Geometric mean approximation:

$$w^n \approx w^{n-1/2} w^{n+1/2}.$$

For $|u'|u'|$:

$$[u'|u'|]^n \approx u'(t_n + \frac{1}{2})|u'(t_n - \frac{1}{2})|.$$

For u' at $t_{n\pm 1/2}$ we use centered difference:

$$u'(t_{n+1/2}) \approx [D_t u]^{n+1/2}, \quad u'(t_{n-1/2}) \approx [D_t u]^{n-1/2}. \quad (53)$$

After some algebra:

$$u^{n+1} = (m + b|u^n - u^{n-1}|)^{-1} \times \\ (2mu^n - mu^{n-1} + bu^n|u^n - u^{n-1}| + \Delta t^2(F^n - s(u^n))) . \quad (54)$$

Initial condition for quadratic damping

Simply use that $u' = V$ in the scheme:

$$[mD_t D_t u + bV|V| + s(u) = F]^0 \quad (55)$$

which gives

$$u^1 = u^0 + \Delta t V + \frac{\Delta t^2}{2m} (-bV|V| - s(u^0) + F^0) . \quad (56)$$

The computational algorithm is a slight variation of the one in Section ??:

- ❶ $u^0 = I$
- ❷ compute u^1 from (51) if linear damping or (56) if quadratic damping
- ❸ for $n = 1, 2, \dots, N_t - 1$:
 - ❶ compute u^{n+1} from (48) if linear damping or (54) if quadratic damping

Implementation

```
def solver(I, V, m, b, s, F, dt, T, damping='linear'):
    """
    Solve  $m u'' + f(u') + s(u) = F(t)$  for  $t$  in  $(0, T]$ ,
     $u(0)=I$  and  $u'(0)=V$ ,
    by a central finite difference method with time step  $dt$ .
    If damping is 'linear',  $f(u')=b*u$ , while if damping is
    'quadratic',  $f(u')=b*u'*abs(u')$ .
     $F(t)$  and  $s(u)$  are Python functions.
    """
    dt = float(dt); b = float(b); m = float(m) # avoid integer div.
    Nt = int(round(T/dt))
    u = zeros(Nt+1)
    t = linspace(0, Nt*dt, Nt+1)

    u[0] = I
    if damping == 'linear':
        u[1] = u[0] + dt*V + dt**2/(2*m)*(-b*V - s(u[0]) + F(t[0]))
    elif damping == 'quadratic':
        u[1] = u[0] + dt*V + \
            dt**2/(2*m)*(-b*V*abs(V) - s(u[0]) + F(t[0]))

    for n in range(1, Nt):
        if damping == 'linear':
            u[n+1] = (2*m*u[n] + (b*dt/2 - m)*u[n-1] +
                      dt**2*(F(t[n]) - s(u[n])))/(m + b*dt/2)
        elif damping == 'quadratic':
            u[n+1] = (2*m*u[n] - m*u[n-1] + b*u[n]*abs(u[n] - u[n-1])
                      + dt**2*(F(t[n]) - s(u[n])))/\
```

- Exact linear solution of the discrete equations with linear s
- MMS

Demo program

vib.py supports input via the command line:

```
Terminal> python vib.py --s 'sin(u)' --F '3*cos(4*t)' --c 0.03
```

This results in a moving window following the function on the screen.
