Purpose.

Truncation error analysis provides a widely applicable framework for analyzing the accuracy of finite difference schemes. This type of analysis can also be used for finite element and finite volume methods if the discrete equations are written in finite difference form. The result of the analysis is an asymptotic estimate of the error in the scheme on the form Ch^r, where h is a discretization parameter (Δt, Δx, etc.), r is a number, known as the convergence rate, and C is a constant, typically dependent on derivatives of the exact solution.

Knowing r gives understanding of the accuracy of the scheme. But maybe even more important, a powerful verification method for computer codes is to check that the empirically observed convergence rates in experiments coincide with the theoretical value of r found from truncation error analysis.

The analysis can be carried out by hand, by symbolic software, and also numerically. All three methods will be illustrated. From examining the symbolic expressions of the truncation error we can add correction terms to the differential equations in order to increase the numerical accuracy.

In general, the term truncation error refers to the discrepancy that arises from performing a finite number of steps to approximate a process with infinitely many steps. The term is used in a number of contexts, including truncation of infinite series, finite precision arithmetic, finite differences, and differential equations. We shall be concerned with computing truncation errors arising in finite difference formulas and in finite difference discretizations of differential equations.

1 Overview of truncation error analysis

1.1 Abstract problem setting

Consider an abstract differential equation

$$\mathcal{L}(u) = 0,$$

where $\mathcal{L}(u)$ is some formula involving the unknown u and its derivatives. One example is $\mathcal{L}(u) = u'(t) + a(t)u(t) - b(t)$, where a and b are contants or functions of time. We can discretize the differential equation and obtain a corresponding discrete model, here written as

$$\mathcal{L}_\Delta(u) = 0\,.$$

The solution u of this equation is the *numerical solution*. To distinguish the numerical solution from the exact solution of the differential equation problem, we denote the latter by u_{e} and write the differential equation and its discrete counterpart as

$$\mathcal{L}(u_{\mathrm{e}}) = 0,$$
$$\mathcal{L}_{\Delta}(u) = 0 \,.$$

...itial and/or boundary conditions can usually be left out of the truncation error ...nalysis and are omitted in the following.

The numerical solution u is in a finite difference method computed at a collec-...on of mesh points. The discrete equations represented by the abstract equation $_\Delta(u) = 0$ are usually algebraic equations involving u at some neighboring mesh ...oints.

.2 Error measures

... key issue is how accurate the numerical solution is. The ultimate way of ...ddressing this issue would be to compute the error $u_{\mathrm{e}} - u$ at the mesh points. ...his is usually extremely demanding. In very simplified problem settings we ...ay, however, manage to derive formulas for the numerical solution u, and ...erefore closed form expressions for the error $u_{\mathrm{e}} - u$. Such special cases can ...rovide considerable insight regarding accuracy and stability, but the results are ...stablished for special problems.

The error $u_{\mathrm{e}} - u$ can be computed empirically in special cases where we know ...e. Such cases can be constructed by the method of manufactured solutions, ...here we choose some exact solution $u_{\mathrm{e}} = v$ and fit a source term f in the ...overning differential equation $\mathcal{L}(u_{\mathrm{e}}) = f$ such that $u_{\mathrm{e}} = v$ is a solution (i.e., $f = $ ...(v)). Assuming an error model of the form Ch^r, where h is the discretization ...arameter, such as Δt or Δx, one can estimate the convergence rate r. This is a ...idely applicable procedure, but the valididity of the results is, strictly speaking, ...ed to the chosen test problems.

Another error measure is to ask to what extent the exact solution u_{e} fits the ...iscrete equations. Clearly, u_{e} is in general not a solution of $\mathcal{L}_{\Delta}(u) = 0$, but we ...an define the residual

$$R = \mathcal{L}_{\Delta}(u_{\mathrm{e}}),$$

...nd investigate how close R is to zero. A small R means intuitively that the ...iscrete equations are close to the differential equation, and then we are tempted ...o think that u^n must also be close to $u_{\mathrm{e}}(t_n)$.

The residual R is known as the truncation error of the finite difference scheme $_\Delta(u) = 0$. It appears that the truncation error is relatively straightforward ...o compute by hand or symbolic software *without specializing the differential ...quation and the discrete model to a special case*. The resulting R is found ...s a power series in the discretization parameters. The leading-order terms ...n the series provide an asymptotic measure of the accuracy of the numerical ...olution method (as the discretization parameters tend to zero). An advantage ...f truncation error analysis compared empricial estimation of convergence rates ...r detailed analysis of a special problem with a mathematical expression for the ...umerical solution, is that the truncation error analysis reveals the accuracy

of the various building blocks in the numerical method and how each ...block impacts the overall accuracy. The analysis can therefore be used t...building blocks with lower accuracy than the others.

Knowing the truncation error or other error measures is important for ...tion of programs by empirically establishing convergence rates. The forth...text will provide many examples on how to compute truncation errors f...difference discretizations of ODEs and PDEs.

2 Truncation errors in finite difference form...

The accuracy of a finite difference formula is a fundamental issue when disc...differential equations. We shall first go through a particular example i...and thereafter list the truncation error in the most common finite di...approximation formulas.

2.1 Example: The backward difference for $u'(t)$

Consider a backward finite difference approximation of the first-order de...u':

$$[D_t^- u]^n = \frac{u^n - u^{n-1}}{\Delta t} \approx u'(t_n) \,.$$

Here, u^n means the value of some function $u(t)$ at a point t_n, and $[L$...the *discrete derivative* of $u(t)$ at $t = t_n$. The discrete derivative comput...finite difference is not exactly equal to the derivative $u'(t_n)$. The erro...approximation is

$$R^n = [D_t^- u]^n - u'(t_n) \,.$$

The common way of calculating R^n is to

1. expand $u(t)$ in a Taylor series around the point where the deriv...
   evaluated, here t_n,

2. insert this Taylor series in (2), and

3. collect terms that cancel and simplify the expression.

The result is an expression for R^n in terms of a power series in Δt. The e...is commonly referred to as the *truncation error* of the finite difference ...

The Taylor series formula often found in calculus books takes the fo...

$$f(x + h) = \sum_{i=0}^{\infty} \frac{1}{i!} \frac{d^i f}{dx^i}(x) h^i \,.$$

In our application, we expand the Taylor series around the point where t...difference formula approximates the derivative. The Taylor series of u...

simply $u(t_n)$, while the Taylor sereis of u^{n-1} at t_n must employ the general formula,

$$u(t_{n-1}) = u(t - \Delta t) = \sum_{i=0}^{\infty} \frac{1}{i!} \frac{d^i u}{dt^i}(t_n)(-\Delta t)^i$$

$$= u(t_n) - u'(t_n)\Delta t + \frac{1}{2}u''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^3),$$

here $\mathcal{O}(\Delta t^3)$ means a power-series in Δt where the lowest power is Δt^3. We ssume that Δt is small such that $\Delta t^p \gg \Delta t^q$ if p is smaller than q. The details f higher-order terms in Δt are therefore not of much interest. Inserting the aylor series above in the left-hand side of1 (2) gives rise to some algebra:

$$\mathcal{D}_t^- u]^n - u'(t_n) = \frac{u(t_n) - u(t_{n-1})}{\Delta t} - u'(t_n)$$

$$= \frac{u(t_n) - (u(t_n) - u'(t_n)\Delta t + \frac{1}{2}u''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^3))}{\Delta t} - u'(t_n)$$

$$= -\frac{1}{2}u''(t_n)\Delta t + \mathcal{O}(\Delta t^2)),$$

hich is, according to (2), the truncation error:

$$R^n = -\frac{1}{2}u''(t_n)\Delta t + \mathcal{O}(\Delta t^2). \tag{3}$$

he dominating term for small Δt is $-\frac{1}{2}u''(t_n)\Delta t$, which is proportional to Δt, nd we say that the truncation error is of *first order* in Δt.

.2 Example: The forward difference for $u'(t)$

Ve can analyze the approximation error in the forward difference

$$u'(t_n) \approx [D_t^+ u]^n = \frac{u^{n+1} - u^n}{\Delta t},$$

y writing

$$R^n = [D_t^+ u]^n - u'(t_n),$$

nd expanding u^{n+1} in a Taylor series around t_n,

$$u(t_{n+1}) = u(t_n) + u'(t_n)\Delta t + \frac{1}{2}u''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^3).$$

he result becomes

$$R = \frac{1}{2}u''(t_n)\Delta t + \mathcal{O}(\Delta t^2),$$

nowing that also the forward difference is of first order.

2.3 Example: The central difference for $u'(t)$

For the central difference approximation,

$$u'(t_n) \approx [D_t u]^n, \quad [D_t u]^n = \frac{u^{n+\frac{1}{2}} - u^{n-\frac{1}{2}}}{\Delta t},$$

we write

$$R^n = [D_t u]^n - u'(t_n),$$

and expand $u(t_{n+\frac{1}{2}})$ and $u(t_{n-1/2})$ in Taylor series around the point t the derivative is evaluated. We have

$$u(t_{n+\frac{1}{2}}) = u(t_n) + u'(t_n)\frac{1}{2}\Delta t + \frac{1}{2}u''(t_n)(\frac{1}{2}\Delta t)^2 +$$

$$\frac{1}{6}u'''(t_n)(\frac{1}{2}\Delta t)^3 + \frac{1}{24}u''''(t_n)(\frac{1}{2}\Delta t)^4 +$$

$$\frac{1}{120}u'''''(t_n)(\frac{1}{2}\Delta t)^5 + \mathcal{O}(\Delta t^6),$$

$$u(t_{n-1/2}) = u(t_n) - u'(t_n)\frac{1}{2}\Delta t + \frac{1}{2}u''(t_n)(\frac{1}{2}\Delta t)^2 -$$

$$\frac{1}{6}u'''(t_n)(\frac{1}{2}\Delta t)^3 + \frac{1}{24}u''''(t_n)(\frac{1}{2}\Delta t)^4 -$$

$$\frac{1}{120}u'''''(t_n)(\frac{1}{2}\Delta t)^5 + \mathcal{O}(\Delta t^6).$$

Now,

$$u(t_{n+\frac{1}{2}}) - u(t_{n-1/2}) = u'(t_n)\Delta t + \frac{1}{24}u'''(t_n)\Delta t^3 + \frac{1}{960}u'''''(t_n)\Delta t^5 + \mathcal{C}$$

By collecting terms in $[D_t u]^n - u(t_n)$ we find the truncation error to be

$$R^n = \frac{1}{24}u'''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4),$$

with only even powers of Δt. Since $R \sim \Delta t^2$ we say the centered differer *second order* in Δt.

2.4 Overview of leading-order error terms in finite ence formulas

Here we list the leading-order terms of the truncation errors associat several common finite difference formulas for the first and second deriva

$$[D_t u]^n = \frac{u^{n+\frac{1}{2}} - u^{n-\frac{1}{2}}}{\Delta t} = u'(t_n) + R^n, \tag{5}$$

$$R^n = \frac{1}{24} u'''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4) \tag{6}$$

$$[D_{2t} u]^n = \frac{u^{n+1} - u^{n-1}}{2\Delta t} = u'(t_n) + R^n, \tag{7}$$

$$R^n = \frac{1}{6} u'''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4) \tag{8}$$

$$[D_t^- u]^n = \frac{u^n - u^{n-1}}{\Delta t} = u'(t_n) + R^n, \tag{9}$$

$$R^n = -\frac{1}{2} u''(t_n)\Delta t + \mathcal{O}(\Delta t^2) \tag{10}$$

$$[D_t^+ u]^n = \frac{u^{n+1} - u^n}{\Delta t} = u'(t_n) + R^n, \tag{11}$$

$$R^n = \frac{1}{2} u''(t_n)\Delta t + \mathcal{O}(\Delta t^2) \tag{12}$$

$$[\bar{D}_t u]^{n+\theta} = \frac{u^{n+1} - u^n}{\Delta t} = u'(t_{n+\theta}) + R^{n+\theta}, \tag{13}$$

$$R^{n+\theta} = \frac{1}{2}(1-2\theta)u''(t_{n+\theta})\Delta t - \frac{1}{6}((1-\theta)^3 - \theta^3)u'''(t_{n+\theta})\Delta t^2 + \mathcal{O}(\Delta t^3) \tag{14}$$

$$[D_t^{2-} u]^n = \frac{3u^n - 4u^{n-1} + u^{n-2}}{2\Delta t} = u'(t_n) + R^n, \tag{15}$$

$$R^n = -\frac{1}{3} u'''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^3) \tag{16}$$

$$[D_t D_t u]^n = \frac{u^{n+1} - 2u^n + u^{n-1}}{\Delta t^2} = u''(t_n) + R^n, \tag{17}$$

$$R^n = \frac{1}{12} u''''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4) \tag{18}$$

It will also be convenient to have the truncation errors for various means or averages. The weighted arithmetic mean leads to

$$[\overline{u}^{t,\theta}]^{n+\theta} = \theta u^{n+1} + (1-\theta)u^n = u(t_{n+\theta}) + R^{n+\theta}, \tag{19}$$

$$R^{n+\theta} = \frac{1}{2} u''(t_{n+\theta})\Delta t^2 \theta(1-\theta) + \mathcal{O}(\Delta t^3). \tag{20}$$

he standard arithmetic mean follows from this formula when $\theta = 1/2$. Expressed t point t_n we get

$$[\overline{u}^t]^n = \frac{1}{2}(u^{n-\frac{1}{2}} + u^{n+\frac{1}{2}}) = u(t_n) + R^n, \tag{21}$$

$$R^n = \frac{1}{8} u''(t_n)\Delta t^2 + \frac{1}{384} u''''(t_n)\Delta t^4 + \mathcal{O}(\Delta t^6). \tag{22}$$

The geometric mean also has an error $\mathcal{O}(\Delta t^2)$:

$$[\overline{u^2}^{t,g}]^n = u^{n-\frac{1}{2}} u^{n+\frac{1}{2}} = (u^n)^2 + R^n,$$

$$R^n = -\frac{1}{4} u'(t_n)^2 \Delta t^2 + \frac{1}{4} u(t_n)u''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4).$$

The harmonic mean is also second-order accurate:

$$[\overline{u}^{t,h}]^n = u^n = \frac{2}{\frac{1}{u^{n-\frac{1}{2}}} + \frac{1}{u^{n+\frac{1}{2}}}} + R^{n+\frac{1}{2}},$$

$$R^n = -\frac{u'(t_n)^2}{4u(t_n)}\Delta t^2 + \frac{1}{8} u''(t_n)\Delta t^2.$$

2.5 Software for computing truncation errors

We can use `sympy` to aid calculations with Taylor series. The derivati be defined as symbols, say `D3f` for the 3rd derivative of some functic truncated Taylor series can then be written as `f + D1f*h + D2f*h**2` following class takes some symbol `f` for the function in question and mak of symbols for the derivatives. The `__call__` method computes the s form of the series truncated at `num_terms` terms.

```python
import sympy as sm

class TaylorSeries:
    """Class for symbolic Taylor series."""
    def __init__(self, f, num_terms=4):
        self.f = f
        self.N = num_terms
        # Introduce symbols for the derivatives
        self.df = [f]
        for i in range(1, self.N+1):
            self.df.append(sm.Symbol('D%d%s' % (i, f.name)))

    def __call__(self, h):
        """Return the truncated Taylor series at x+h."""
        terms = self.f
        for i in range(1, self.N+1):
            terms += sm.Rational(1, sm.factorial(i))*self.df[i]*h
        return terms
```

We may, for example, use this class to compute the truncation erro Forward Euler finite difference formula:

```python
>>> from truncation_errors import TaylorSeries
>>> from sympy import *
>>> u, dt = symbols('u dt')
>>> u_Taylor = TaylorSeries(u, 4)
>>> u_Taylor(dt)
D1u*dt + D2u*dt**2/2 + D3u*dt**3/6 + D4u*dt**4/24 + u
>>> FE = (u_Taylor(dt) - u)/dt
```

```
>>> FE
(D1u*dt + D2u*dt**2/2 + D3u*dt**3/6 + D4u*dt**4/24)/dt
>>> simplify(FE)
D1u + D2u*dt/2 + D3u*dt**2/6 + D4u*dt**3/24
```

The truncation error consists of the terms after the first one (u').

The module file trunc/truncation_errors.py[1] contains another class DiffOp with symbolic expressions for most of the truncation errors listed in the previous section. For example:

```
>>> from truncation_errors import DiffOp
>>> from sympy import *
>>> u = Symbol('u')
>>> diffop = DiffOp(u, independent_variable='t')
>>> diffop['geometric_mean']
-D1u**2*dt**2/4 - D1u*D3u*dt**4/48 + D2u**2*dt**4/64 + ...
>>> diffop['Dtm']
D1u + D2u*dt/2 + D3u*dt**2/6 + D4u*dt**3/24
>>> >>> diffop.operator_names()
['geometric_mean', 'harmonic_mean', 'Dtm', 'D2t', 'DtDt',
 'weighted_arithmetic_mean', 'Dtp', 'Dt']
```

The indexing of diffop applies names that correspond to the operators: Dtp for D_t^+, Dtm for D_t^-, Dt for D_t, D2t for D_{2t}, DtDt for D_tD_t.

Truncation errors in exponential decay ODE

We shall now compute the truncation error of a finite difference scheme for a differential equation. Our first problem involves the following the linear ODE modeling exponential decay,

$$u'(t) = -au(t).\qquad(27)$$

.1 Truncation error of the Forward Euler scheme

We begin with the Forward Euler scheme for discretizing (27):

$$[D_t^+u = -au]^n.\qquad(28)$$

The idea behind the truncation error computation is to insert the exact solution u_e of the differential equation problem (27) in the discrete equations (28) and and the residual that arises because u_e does not solve the discrete equations. Instead, u_e solves the discrete equations with a residual R^n:

$$[D_t^+u_e + au_e = R]^n.\qquad(29)$$

From (11)-(12) it follows that

$$[D_t^+u_e]^n = u'_e(t_n) + \frac{1}{2}u''_e(t_n)\Delta t + \mathcal{O}(\Delta t^2),$$

[1] http://tinyurl.com/jvzzcfn/trunc/truncation_errors.py

which inserted in (29) results in

$$u'_e(t_n) + \frac{1}{2}u''_e(t_n)\Delta t + \mathcal{O}(\Delta t^2) + au_e(t_n) = R^n.$$

Now, $u'_e(t_n) + au_e^n = 0$ since u_e solves the differential equation. The re- terms constitute the residual:

$$R^n = \frac{1}{2}u''_e(t_n)\Delta t + \mathcal{O}(\Delta t^2).$$

This is the truncation error R^n of the Forward Euler scheme.

Because R^n is proportional to Δt, we say that the Forward Euler is of first order in Δt. However, the truncation error is just one error m and it is not equal to the true error $u_e^n - u^n$. For this simple model p we can compute a range of different error measures for the Forwar scheme, including the true error $u_e^n - u^n$, and all of them have dominatin proportional to Δt.

3.2 Truncation error of the Crank-Nicolson scheme

For the Crank-Nicolson scheme,

$$[D_tu = -au]^{n+\frac{1}{2}},$$

we compute the truncation error by inserting the exact solution of the O adding a residual R,

$$[D_tu_e + a\overline{u_e}^t = R]^{n+\frac{1}{2}}.$$

The term $[D_tu_e]^{n+\frac{1}{2}}$ is easily computed from (5)-(6) by replacing n wit in the formula,

$$[D_tu_e]^{n+\frac{1}{2}} = u'(t_{n+\frac{1}{2}}) + \frac{1}{24}u'''_e(t_{n+\frac{1}{2}})\Delta t^2 + \mathcal{O}(\Delta t^4).$$

The arithmetic mean is related to $u(t_{n+\frac{1}{2}})$ by (21)-(22) so

$$[a\overline{u_e}^t]^{n+\frac{1}{2}} = u(t_{n+\frac{1}{2}}) + \frac{1}{8}u''(t_n)\Delta t^2 + +\mathcal{O}(\Delta t^4).$$

Inserting these expressions in (32) and observing that $u'_e(t_{n+\frac{1}{2}}) + au_e^n$ because $u_e(t)$ solves the ODE $u'(t) = -au(t)$ at any point t, we find th

$$R^{n+\frac{1}{2}} = \left(\frac{1}{24}u'''_e(t_{n+\frac{1}{2}}) + \frac{1}{8}u''(t_n)\right)\Delta t^2 + \mathcal{O}(\Delta t^4)$$

Here, the truncation error is of second order because the leading term proportional to Δt^2.

At this point it is wise to redo some of the computations above to e the truncation error of the Backward Euler scheme, see Exercise 4.

.3 Truncation error of the θ-rule

We may also compute the truncation error of the θ-rule,

$$[\bar{D}_t u = -a\overline{u}^{t,\theta}]^{n+\theta}.$$

Our computational task is to find $R^{n+\theta}$ in

$$[\bar{D}_t u_{\mathrm{e}} + a\overline{u_{\mathrm{e}}}^{t,\theta} = R]^{n+\theta}.$$

From (13)-(14) and (19)-(20) we get expressions for the terms with u_{e}. Using that $u'_{\mathrm{e}}(t_{n+\theta}) + au_{\mathrm{e}}(t_{n+\theta}) = 0$, we end up with

$$R^{n+\theta} = (\frac{1}{2} - \theta)u''_{\mathrm{e}}(t_{n+\theta})\Delta t + \frac{1}{2}\theta(1-\theta)u''_{\mathrm{e}}(t_{n+\theta})\Delta t^2 +$$
$$\frac{1}{2}(\theta^2 - \theta + 3)u'''_{\mathrm{e}}(t_{n+\theta})\Delta t^2 + \mathcal{O}(\Delta t^3) \quad (34)$$

For $\theta = 1/2$ the first-order term vanishes and the scheme is of second order, while for $\theta \neq 1/2$ we only have a first-order scheme.

.4 Using symbolic software

The previously mentioned `truncation_error` module can be used to automate the Taylor series expansions and the process of collecting terms. Here is an example on possible use:

```
from truncation_error import DiffOp
from sympy import *

def decay():
    u, a = symbols('u a')
    diffop = DiffOp(u, independent_variable='t',
                    num_terms_Taylor_series=3)
    D1u = diffop.D(1)    # symbol for du/dt
    ODE = D1u + a*u      # define ODE

    # Define schemes
    FE = diffop['Dtp'] + a*u
    CN = diffop['Dt' ] + a*u
    BE = diffop['Dtm'] + a*u
    theta = diffop['barDt'] + a*diffop['weighted_arithmetic_mean']
    theta = sm.simplify(sm.expand(theta))
    # Residuals (truncation errors)
    R = {'FE': FE-ODE, 'BE': BE-ODE, 'CN': CN-ODE,
         'theta': theta-ODE}
    return R
```

The returned dictionary becomes

```
decay: {
  'BE': D2u*dt/2 + D3u*dt**2/6,
  'FE': -D2u*dt/2 + D3u*dt**2/6,
  'CN': D3u*dt**2/24,
  'theta': -D2u*a*dt**2*theta**2/2 + D2u*a*dt**2*theta/2 -
           D2u*dt*theta + D2u*dt/2 + D3u*a*dt**3*theta**3/3 -
           D3u*a*dt**3*theta**2/2 + D3u*a*dt**3*theta/6 +
           D3u*dt**2*theta**2/2 - D3u*dt**2*theta/2 + D3u*dt**2/6,
}
```

The results are in correspondence with our hand-derived expressions.

3.5 Empirical verification of the truncation error

The task of this section is to demonstrate how we can compute the tru
error R numerically. For example, the truncation error of the Forwar
scheme applied to the decay ODE $u' = -ua$ is

$$R^n = [D_t^+ u_{\mathrm{e}} + au_{\mathrm{e}}]^n.$$

If we happen to know the exact solution $u_{\mathrm{e}}(t)$, we can easily evaluate R
the above formula.

To estimate how R varies with the discretization parameter Δt, wh
been our focus in the previous mathematical derivations, we first m
assumption that $R = C\Delta t^r$ for appropriate constants C and r and small
Δt. The rate r can be estimated from a series of experiments where Δt i
Suppose we have m experiments $(\Delta t_i, R_i)$, $i = 0, \ldots, m-1$. For two con
experiments $(\Delta t_{i-1}, R_{i-1})$ and $(\Delta t_i, R_i)$, a corresponding r_{i-1} can be es
by

$$r_{i-1} = \frac{\ln(R_{i-1}/R_i)}{\ln(\Delta t_{i-1}/\Delta t_i)},$$

for $i = 1, \ldots, m-1$. Note that the truncation error R_i varies through th
so (36) is to be applied pointwise. A complicating issue is that R_i and R_i
to different meshes. Pointwise comparisons of the truncation error at a
point in all meshes therefore requires any computed R to be restricted
coarsest mesh and that all finer meshes contain all the points in the
mesh. Suppose we have N_0 intervals in the coarsest mesh. Inserting a sup
n in (36), where n counts mesh points in the coarsest mesh, $n = 0, \ldots, N$
to the formula

$$r_{i-1}^n = \frac{\ln(R_{i-1}^n/R_i^n)}{\ln(\Delta t_{i-1}/\Delta t_i)}.$$

Experiments are most conveniently defined by N_0 and a number of refin
m. Suppose each mesh have twice as many cells N_i as the previous one

$$N_i = 2^i N_0, \quad \Delta t_i = TN_i^{-1},$$

where $[0, T]$ is the total time interval for the computations. Suppose the co
R_i values on the mesh with N_i intervals are stored in an array `R[i]` (R
list of arrays, one for each mesh). Restricting this R_i function to the
mesh means extracting every N_i/N_0 point and is done as follows:

```
stride = N[i]/N_0
R[i] = R[i][::stride]
```

The quantity `R[i][n]` now corresponds to R_i^n.

In addition to estimating r for the pointwise values of $R = C\Delta t^r$, we may also consider an integrated quantity on mesh i,

$$R_{I,i} = \left(\Delta t_i \sum_{n=0}^{N_i} (R_i^n)^2\right)^{\frac{1}{2}} \approx \int_0^T R_i(t)dt\,. \tag{38}$$

The sequence $R_{I,i}$, $i = 0,\ldots,m-1$, is also expected to behave as $C\Delta t^r$, with the same r as for the pointwise quantity R, as $\Delta t \to 0$.

The function below computes the R_i and $R_{I,i}$ quantities, plots them and compares with the theoretically derived truncation error (`R_a`) if available.

```python
import numpy as np
import scitools.std as plt

def estimate(truncation_error, T, N_0, m, makeplot=True):
    """
    Compute the truncation error in a problem with one independent
    variable, using m meshes, and estimate the convergence
    rate of the truncation error.

    The user-supplied function truncation_error(dt, N) computes
    the truncation error on a uniform mesh with N intervals of
    length dt::

      R, t, R_a = truncation_error(dt, N)

    where R holds the truncation error at points in the array t,
    and R_a are the corresponding theoretical truncation error
    values (None if not available).

    The truncation_error function is run on a series of meshes
    with 2**i*N_0 intervals, i=0,1,...,m-1.
    The values of R and R_a are restricted to the coarsest mesh.
    and based on these data, the convergence rate of R (pointwise)
    and time-integrated R can be estimated empirically.
    """
    N = [2**i*N_0 for i in range(m)]

    R_I = np.zeros(m) # time-integrated R values on various meshes
    R   = [None]*m    # time series of R restricted to coarsest mesh
    R_a = [None]*m    # time series of R_a restricted to coarsest mesh
    dt = np.zeros(m)
    legends_R = [];  legends_R_a = []  # all legends of curves

    for i in range(m):
        dt[i] = T/float(N[i])
        R[i], t, R_a[i] = truncation_error(dt[i], N[i])

        R_I[i] = np.sqrt(dt[i]*np.sum(R[i]**2))

        if i == 0:
            t_coarse = t           # the coarsest mesh

        stride = N[i]/N_0
        R[i] = R[i][::stride]       # restrict to coarsest mesh
        R_a[i] = R_a[i][::stride]
```

```python
        if makeplot:
            plt.figure(1)
            plt.plot(t_coarse, R[i], log='y')
            legends_R.append('N=%d' % N[i])
            plt.hold('on')

            plt.figure(2)
            plt.plot(t_coarse, R_a[i] - R[i], log='y')
            plt.hold('on')
            legends_R_a.append('N=%d' % N[i])

    if makeplot:
        plt.figure(1)
        plt.xlabel('time')
        plt.ylabel('pointwise truncation error')
        plt.legend(legends_R)
        plt.savefig('R_series.png')
        plt.savefig('R_series.pdf')
        plt.figure(2)
        plt.xlabel('time')
        plt.ylabel('pointwise error in estimated truncation error')
        plt.legend(legends_R_a)
        plt.savefig('R_error.png')
        plt.savefig('R_error.pdf')

    # Convergence rates
    r_R_I = convergence_rates(dt, R_I)
    print 'R integrated in time; r:',
    print ' '.join(['%.1f' % r for r in r_R_I])
    R = np.array(R)  # two-dim. numpy array
    r_R = [convergence_rates(dt, R[:,n])[-1]
           for n in range(len(t_coarse))]
```

The first `makeplot` block demonstrates how to build up two figures in using `plt.figure(i)` to create and switch to figure number `i`. Figure start at 1. A logarithmic scale is used on the y axis since we expect as a function of time (or mesh points) is exponential. The reason is t theoretical estimate (30) contains u_e'', which for the present model goes l Taking the logarithm makes a straight line.

The code follows closely the previously stated mathematical formulas, statements for computing the convergence rates might deserve an expl The generic help function `convergence_rate(h, E)` computes and retu $i = 1,\ldots,m-1$ from (37), given Δt_i in `h` and R_i^n in `E`:

```python
def convergence_rates(h, E):
    from math import log
    r = [log(E[i]/E[i-1])/log(h[i]/h[i-1])
         for i in range(1, len(h))]
    return r
```

Calling `r_R_I = convergence_rates(dt, R_I)` computes the seq rates $r_0, r_1,\ldots,r_{m-2}$ for the model $R_I \sim \Delta t^r$, while the statements

```
t = np.array(R)  # two-dim. numpy array
r_R = [convergence_rates(dt, R[:,n])[-1]
       for n in range(len(t_coarse))]
```

ompute the final rate r_{m-2} for $R^n \sim \Delta t^r$ at each mesh point t_n in the coarsest mesh. This latter computation deserves more explanation. Since `R[i][n]` holds ne estimated truncation error R_i^n on mesh i, at point t_n in the coarsest mesh, [:,n] picks out the sequence R_i^n for $i = 0, \ldots, m-1$. The `convergence_rate` nction computes the rates at t_n, and by indexing `[-1]` on the returned array om `convergence_rate`, we pick the rate r_{m-2}, which we believe is the best stimation since it is based on the two finest meshes.

The `estimate` function is available in a module `trunc_empir.py`[2]. Let us pply this function to estimate the truncation error of the Forward Euler scheme. We need a function `decay_FE(dt, N)` that can compute (35) at the points in a nesh with time step `dt` and N intervals:

```python
import numpy as np
import trunc_empir

def decay_FE(dt, N):
    dt = float(dt)
    t = np.linspace(0, N*dt, N+1)
    u_e = I*np.exp(-a*t)  # exact solution, I and a are global
    u = u_e  # naming convention when writing up the scheme
    R = np.zeros(N)

    for n in range(0, N):
        R[n] = (u[n+1] - u[n])/dt + a*u[n]

        # Theoretical expression for the trunction error
        R_a = 0.5*I*(-a)**2*np.exp(-a*t)*dt

    return R, t[:-1], R_a[:-1]

if __name__ == '__main__':
    I = 1; a = 2  # global variables needed in decay_FE
    trunc_empir.estimate(decay_FE, T=2.5, N_0=6, m=4, makeplot=True)
```

The estimated rates for the integrated truncation error R_I become 1.1, 1.0, nd 1.0 for this sequence of four meshes. All the rates for R^n, computed as _R, are also very close to 1 at all mesh points. The agreement between the neoretical formula (30) and the computed quantity (ref(35)) is very good, as lustrated in Figures 1 and 2. The program `trunc_decay_FE.py`[3] was used to erform the simulations and it can easily be modified to test other schemes (see lso Exericse 5).

.6 Increasing the accuracy by adding correction terms

ow we ask the question: can we add terms in the differential equation that an help increase the order of the truncation error? To be precise, let us revisit

---

[2]http://tinyurl.com/jvzzcfn/trunc/trunc_empir.py
[3]http://tinyurl.com/jvzzcfn/trunc/trunc_decay_FE.py

Figure 1: Estimated truncation error at mesh points for different me

the Forward Euler scheme for $u' = -au$, insert the exact solution u_e, in residual R, but also include new terms C:

$$[D_t^+ u_e + au_e = C + R]^n.$$

Inserting the Taylor expansions for $[D_t^+ u_e]^n$ and keeping terms up to 3 in Δt gives the equation

$$\frac{1}{2}u_e''(t_n)\Delta t - \frac{1}{6}u_e'''(t_n)\Delta t^2 + \frac{1}{24}u_e''''(t_n)\Delta t^3 + \mathcal{O}(\Delta t^4) = C^n + R^n$$

Can we find C^n such that R^n is $\mathcal{O}(\Delta t^2)$? Yes, by setting

$$C^n = \frac{1}{2}u_e''(t_n)\Delta t,$$

we manage to cancel the first-order term and

$$R^n = \frac{1}{6}u_e'''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^3).$$

The correction term C^n introduces $\frac{1}{2}\Delta t u''$ in the discrete equati we have to get rid of the derivative u''. One idea is to approximate second-order accurate finite difference formula, $u'' \approx (u^{n+1} - 2u^n + u^{n-}$ but this introduces an additional time level with u^{n-1}. Another approa rewrite u'' in terms of u' or u using the ODE:
Figure 2: Difference between theoretical and estimated truncation error at mesh points for different meshes.

$$u' = -au \quad \Rightarrow \quad u'' = -au' = -a(-au) = a^2u.$$

This means that we can simply set $C^n = \frac{1}{2}a^2\Delta t u^n$. We can then either solve the discrete equation

$$[D_t^+ u = -au + \frac{1}{2}a^2\Delta t u]^n, \tag{40}$$

or we can equivalently discretize the perturbed ODE

$$u' = -\hat{a}u, \quad \hat{a} = a(1 - \frac{1}{2}a\Delta t), \tag{41}$$

by a Forward Euler method. That is, we replace the original coefficient a by the perturbed coefficient $\hat{a}$. Observe that $\hat{a} \to a$ as $\Delta t \to 0$.

The Forward Euler method applied to (41) results in

$$[D_t^+ u = -a(1 - \frac{1}{2}a\Delta t)u]^n.$$

We can control our computations and verify that the truncation error of the scheme above is indeed $\mathcal{O}(\Delta t^2)$.

Another way of revealing the fact that the perturbed ODE leads to a more accurate solution is to look at the amplification factor. Our scheme can be written as

---

$$u^{n+1} = Au^n, \quad A = 1 - \hat{a}\Delta t = 1 - p + \frac{1}{2}p^2, \quad p = a\Delta t,$$

The amplification factor A as a function of $p = a\Delta t$ is seen to be the fir terms of the Taylor series for the exact amplification factor e^{-p}. The l Euler scheme for $u = -au$ gives only the first two terms $1 - p$ of the Tayl for e^{-p}. That is, using $\hat{a}$ increases the order of the accuracy in the ampl factor.

Instead of replacing u'' by a^2u, we use the relation $u'' = -au'$ an term $-\frac{1}{2}a\Delta t u'$ in the ODE:

$$u' = -au - \frac{1}{2}a\Delta t u' \quad \Rightarrow \quad \left(1 + \frac{1}{2}a\Delta t\right)u' = -au.$$

Using a Forward Euler method results in

$$\left(1 + \frac{1}{2}a\Delta t\right)\frac{u^{n+1} - u^n}{\Delta t} = -au^n,$$

which after some algebra can be written as

$$u^{n+1} = \frac{1 - \frac{1}{2}a\Delta t}{1 + \frac{1}{2}a\Delta t}u^n.$$

This is the same formula as the one arising from a Crank-Nicolson scheme to $u' = -au$! It now recommended to do Exercise 6 and repeat the abo to see what kind of correction term is needed in the Backward Euler sc make it second order.

The Crank-Nicolson scheme is a bit more challenging to analyze, ideas and techniques are the same. The discrete equation reads

$$[D_t u = -au]^{n+\frac{1}{2}},$$

and the truncation error is defined through

$$[D_t u_e + a\overline{u_e}^t = C + R]^{n+\frac{1}{2}},$$

where we have added a correction term. We need to Taylor expand b discrete derivative and the arithmetic mean with aid of (5)-(6) and (2 respectively. The result is

$$\frac{1}{24}u_e'''(t_{n+\frac{1}{2}})\Delta t^2 + \mathcal{O}(\Delta t^4) + \frac{a}{8}u_e''(t_{n+\frac{1}{2}})\Delta t^2 + \mathcal{O}(\Delta t^4) = C^{n+\frac{1}{2}} + R^{'}$$

The goal now is to make $C^{n+\frac{1}{2}}$ cancel the Δt^2 terms:

$$C^{n+\frac{1}{2}} = \frac{1}{24}u_e'''(t_{n+\frac{1}{2}})\Delta t^2 + \frac{a}{8}u_e''(t_n)\Delta t^2.$$

using $u' = -au$, we have that $u'' = a^2 u$, and we find that $u''' = -a^3 u$. We can therefore solve the perturbed ODE problem

$$u' = -\hat{a}u, \quad \hat{a} = a(1 - \frac{1}{12}a^2\Delta t^2),$$

by the Crank-Nicolson scheme and obtain a method that is of fourth order in Δt. Exercise 7 encourages you to implement these correction terms and calculate empirical convergence rates to verify that higher-order accuracy is indeed obtained in real computations.

.7 Extension to variable coefficients

Let us address the decay ODE with variable coefficients,

$$u'(t) = -a(t)u(t) + b(t),$$

discretized by the Forward Euler scheme,

$$[D_t^+ u = -au + b]^n. \tag{42}$$

The truncation error R is as always found by inserting the exact solution $u_e(t)$ in the discrete scheme:

$$[D_t^+ u_e + au_e - b = R]^n. \tag{43}$$

Using (11)-(12),

$$u_e'(t_n) - \frac{1}{2}u_e''(t_n)\Delta t + \mathcal{O}(\Delta t^2) + a(t_n)u_e(t_n) - b(t_n) = R^n.$$

Because of the ODE,

$$u_e'(t_n) + a(t_n)u_e(t_n) - b(t_n) = 0,$$

so we are left with the result

$$R^n = -\frac{1}{2}u_e''(t_n)\Delta t + \mathcal{O}(\Delta t^2). \tag{44}$$

We see that the variable coefficients do not pose any additional difficulties in this case. Exercise 8 takes the analysis above one step further to the Crank-Nicolson scheme.

.8 Exact solutions of the finite difference equations

Having a mathematical expression for the numerical solution is very valuable in program verification since we then know the exact numbers that the program should produce. Looking at the various formulas for the truncation errors in)-(6) and (25)-(26) in Section 2.4, we see that all but two of the R expressions contains a second or higher order derivative of u_e. The exceptions are the geometric and harmonic means where the truncation error involves u_e' and even e in case of the harmonic mean. So, apart from these two means, choosing u_e

to be a linear function of t, $u_e = ct + d$ for constants c and d, will m truncation error vanish since $u_e'' = 0$. Consqeuently, the truncation er finite difference scheme will be zero since the various approximations u all be exact. This means that the linear solution is an exact solutio discrete equations.

In a particular differential equation problem, the reasoning above used to determine if we expect a linear u_e to fulfill the discrete equati actually prove that this is true, we can either compute the truncation er see that it vanishes, or we can simply insert $u_e(t) = ct + d$ in the sche see that it fulfills the equations. The latter method is usually the simp will often be necessary to add some source term to the ODE in order to linear solution.

Many ODEs are discretized by centered differences. From Section see that all the centered difference formulas have truncation errors in u_e''' or higher-order derivatives. A quadratic solution, e.g., $u_e(t) = t^2$ will then make the truncation errors vanish. This observation can to test if a quadratic solution will fulfill the discrete equations. Note quadratic solution will not obey the equations for a Crank-Nicolson sch $u' = -au + b$ because the approximation applies an arithmetic mean involves a truncation error with u_e''.

3.9 Computing truncation errors in nonlinear probl

The general nonlinear ODE

$$u' = f(u, t),$$

can be solved by a Crank-Nicolson scheme

$$[D_t u' = \overline{f}^t]^{n+\frac{1}{2}}.$$

The truncation error is as always defined as the residual arising when i the exact solution u_e in the scheme:

$$[D_t u_e' - \overline{f}^t = R]^{n+\frac{1}{2}}.$$

Using (21)-(22) for $\overline{f}^t$ results in

$$\begin{aligned}
[\overline{f}^t]^{n+\frac{1}{2}} &= \frac{1}{2}(f(u_e^n, t_n) + f(u_e^{n+1}, t_{n+1})) \\
&= f(u_e^{n+\frac{1}{2}}, t_{n+\frac{1}{2}}) + \frac{1}{8}u_e''(t_{n+\frac{1}{2}})\Delta t^2 + \mathcal{O}(\Delta t^4).
\end{aligned}$$

With (5)-(6) the discrete equations (47) lead to

$$u_e'(t_{n+\frac{1}{2}}) + \frac{1}{24}u_e'''(t_{n+\frac{1}{2}})\Delta t^2 - f(u_e^{n+\frac{1}{2}}, t_{n+\frac{1}{2}}) - \frac{1}{8}u_e''(t_{n+\frac{1}{2}})\Delta t^2 + \mathcal{O}(\Delta t^4) =$$

ince $u'_e(t_{n+\frac{1}{2}}) - f(u_e^{n+\frac{1}{2}}, t_{n+\frac{1}{2}}) = 0$, the truncation error becomes

$$R^{n+\frac{1}{2}} = (\frac{1}{24}u'''_e(t_{n+\frac{1}{2}}) - \frac{1}{8}u''(t_{n+\frac{1}{2}}))\Delta t^2.$$

he computational techniques worked well even for this nonlinear ODE.

Truncation errors in vibration ODEs

.1 Linear model without damping

he next example on computing the truncation error involves the following ODE
r vibration problems:

$$u''(t) + \omega^2 u(t) = 0. \tag{48}$$

ere, ω is a given constant.

he truncation error of a centered finite difference scheme. Using a
andard, second-ordered, central difference for the second-order derivative time,
e have the scheme

$$[D_t D_t u + \omega^2 u = 0]^n. \tag{49}$$

Inserting the exact solution u_e in this equation and adding a residual R so
at u_e can fulfill the equation results in

$$[D_t D_t u_e + \omega^2 u_e = R]^n. \tag{50}$$

o calculate the truncation error R^n, we use (17)-(18), i.e.,

$$[D_t D_t u_e]^n = u''_e(t_n) + \frac{1}{12}u''''_e(t_n)\Delta t^2,$$

nd the fact that $u''_e(t) + \omega^2 u_e(t) = 0$. The result is

$$R^n = \frac{1}{12}u''''_e(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4). \tag{51}$$

he truncation error of approximating $u'(0)$. The initial conditions for
8) are $u(0) = I$ and $u'(0) = V$. The latter involves a finite difference approxi-
ation. The standard choice

$$[D_{2t}u = V]^0,$$

here u^{-1} is eliminated with the aid of the discretized ODE for $n = 0$, involves
centered difference with an $\mathcal{O}(\Delta t^2)$ truncation error given by (7)-(8). The
mpler choice

$$[D_t^+ u = V]^0,$$

based on a forward difference with a truncation error $\mathcal{O}(\Delta t)$. A central
uestion is if this initial error will impact the order of the scheme throughout the
mulation. Exercise 11 asks you to quickly perform an experiment to investigate
iis question.

Truncation error of the equation for the first step. We have sho
the truncation error of the difference used to approximate the initial c
$u'(0) = 0$ is $\mathcal{O}(\Delta t^2)$, but can also investigate the difference equation
the first step. In a truncation error setting, the right way to view this e
is not to use the initial condition $[D_{2t}u = V]^0$ to express $u^{-1} = u^1$
in order to eliminate u^{-1} from the discretized differential equation,
other way around: the fundamental equation is the discretized initial c
$[D_{2t}u = V]^0$ and we use the discretized ODE $[D_t D_t + \omega^2 u = 0]^0$ to el
u^{-1} in the disretized initial condition. From $[D_t D_t + \omega^2 u = 0]^0$ we hav

$$u^{-1} = 2u^0 - u^1 - \Delta t^2 \omega^2 u^0,$$

which inserted in $[D_{2t}u = V]^0$ gives

$$\frac{u^1 - u^0}{\Delta t} + \frac{1}{2}\omega^2 \Delta t u^0 = V.$$

The first term can be recognized as a forward difference such that the e
can be written in operator notation as

$$[D_t^+ u + \frac{1}{2}\omega^2 \Delta t u = V]^0.$$

The truncation error is defined as

$$[D_t^+ u_e + \frac{1}{2}\omega^2 \Delta t u_e - V = R]^0.$$

Using (11)-(12) with one more term in the Taylor series, we get that

$$u'_e(0) + \frac{1}{2}u''_e(0)\Delta t + \frac{1}{6}u'''_e(0)\Delta t^2 + \mathcal{O}(\Delta t^3) + \frac{1}{2}\omega^2 \Delta t u_e(0) - V = F$$

Now, $u'_e(0) = V$ and $u''_e(0) = -\omega^2 u_e(0)$ so we get

$$R^n = \frac{1}{6}u'''_e(0)\Delta t^2 + \mathcal{O}(\Delta t^3).$$

There is another way of analyzing the discrete initial condition,
eliminating u^{-1} via the discretized ODE can be expressed as

$$[D_{2t}u + \Delta t(D_t D_t u - \omega^2 u) = V]^0.$$

Writing out (53) shows that the equation is equivalent to (52). The tru
error is defined by

$$[D_{2t}u_e + \Delta t(D_t D_t u_e - \omega^2 u_e) = V + R]^0.$$

Replacing the difference via (7)-(8) and (17)-(18), as well as using u'_e
and $u''_e(0) = -\omega^2 u_e(0)$, gives

$$R^n = \frac{1}{6}u'''(0)\Delta t^2 + \mathcal{O}(\Delta t^3).$$

Computing correction terms. The idea of using correction terms to increase the order of R^n can be applied as described in Section 3.6. We look at

$$[D_t D_t u_e + \omega^2 u_e = C + R]^n,$$

and observe that C^n must be chosen to cancel the Δt^2 term in R^n. That is,

$$C^n = \frac{1}{12} u_e''''(t_n)\Delta t^2.$$

To get rid of the 4th-order derivative we can use the differential equation: $u'' = -\omega^u$, which implies $u'''' = \omega^4 u$. Adding the correction term to the ODE results in

$$u'' + \omega^2(1 - \frac{1}{12}\omega^2\Delta t^2)u = 0. \tag{54}$$

Solving this equation by the standard scheme

$$[D_t D_t u + \omega^2(1 - \frac{1}{12}\omega^2\Delta t^2)u = 0]^n,$$

will result in a scheme with trunction error $\mathcal{O}(\Delta t^4)$.

We can use another set of arguments to justify that (54) leads to a higher-order method. Mathematical analysis of the scheme (49) reveals that the numerical frequency $\tilde{\omega}$ is (approximately as $\Delta t \to 0$)

$$\tilde{\omega} = \omega(1 + \frac{1}{24}\omega^2\Delta t^2).$$

One can therefore attempt to replace ω in the ODE by a slightly smaller ω since the numerics will make it larger:

$$[u'' + (\omega(1 - \frac{1}{24}\omega^2\Delta t^2))^2 u = 0.$$

Expanding the squared term and omitting the higher-order term Δt^4 gives exactly the ODE (54). Experiments show that u^n is computed to 4th order in t.

.2   Model with damping and nonlinearity

The model (48) can be extended to include damping $\beta u'$, a nonlinear restoring (spring) force $s(u)$, and some known excitation force $F(t)$:

$$mu'' + \beta u' + s(u) = F(t). \tag{55}$$

The coefficient m usually represents the mass of the system. This governing equation can by discretized by centered differences:

$$[mD_t D_t u + \beta D_{2t} u + s(u) = F]^n. \tag{56}$$

The exact solution u_e fulfills the discrete equations with a residual term:

$$[mD_t D_t u_e + \beta D_{2t} u_e + s(u_e) = F + R]^n.$$

Using (17)-(18) and (7)-(8) we get

$$[mD_t D_t u_e + \beta D_{2t} u_e]^n = mu_e''(t_n) + \beta u_e'(t_n)+$$
$$\left(\frac{m}{12}u_e''''(t_n) + \frac{\beta}{6}u_e'''(t_n)\right)\Delta t^2 + \mathcal{O}(\Delta t^4)$$

Combining this with the previous equation, we can collect the terms

$$mu_e''(t_n) + \beta u_e'(t_n) + \omega^2 u_e(t_n) + s(u_e(t_n)) - F^n,$$

and set this sum to zero because u_e solves the differential equation. We with the truncation error

$$R^n = \left(\frac{m}{12}u_e''''(t_n) + \frac{\beta}{6}u_e'''(t_n)\right)\Delta t^2 + \mathcal{O}(\Delta t^4),$$

so the scheme is of second order.

According to (58), we can add correction terms

$$C^n = \left(\frac{m}{12}u_e''''(t_n) + \frac{\beta}{6}u_e'''(t_n)\right)\Delta t^2,$$

to the right-hand side of the ODE to obtain a fourth-order scheme. E expressing u'''' and u''' in terms of lower-order derivatives is now harder the differential equation is more complicated:

$$u''' = \frac{1}{m}(F' - \beta u'' - s'(u)u'),$$
$$u'''' = \frac{1}{m}(F'' - \beta u''' - s''(u)(u')^2 - s'(u)u''),$$
$$= \frac{1}{m}(F'' - \beta\frac{1}{m}(F' - \beta u'' - s'(u)u') - s''(u)(u')^2 - s'(u)u'')$$

It is not impossible to discretize the resulting modified ODE, but it i debate whether correction terms are feasible and the way to go. Computi a smaller Δt is usually always possible in these problems to achieve the accuracy.

4.3   Extension to quadratic damping

Instead of the linear damping term $\beta u'$ in (55) we now consider qu damping $\beta|u'|u'$:

$$mu'' + \beta|u'|u' + s(u) = F(t).$$

centered difference for u' gives rise to a nonlinearity, which can be linearized using a geometric mean: $[|u'|u']^n \approx |[u']^{n-\frac{1}{2}}|[u']^{n+\frac{1}{2}}$. The resulting scheme becomes

$$[mD_tD_tu]^n + \beta[D_tu]^{n-\frac{1}{2}}|[D_tu]^{n+\frac{1}{2}} + s(u^n) = F^n. \tag{60}$$

The truncation error is defined through

$$[mD_tD_tu_e]^n + \beta|[D_tu_e]^{n-\frac{1}{2}}|[D_tu_e]^{n+\frac{1}{2}} + s(u_e^n) - F^n = R^n. \tag{61}$$

We start with expressing the truncation error of the geometric mean. According to (23)-(24),

$$D_tu_e]^{n-\frac{1}{2}}|[D_tu_e]^{n+\frac{1}{2}} = [|D_tu_e|D_tu_e]^n - \frac{1}{4}u'(t_n)^2\Delta t^2 + \frac{1}{4}u(t_n)u''(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4).$$

Using (5)-(6) for the D_tu_e factors results in

$$|D_tu_e|D_tu_e]^n = |u'_e + \frac{1}{24}u'''_e(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4)|(u'_e + \frac{1}{24}u'''_e(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4))$$

We can remove the absolute value since it essentially gives a factor 1 or -1 only. Calculating the product, we have the leading-order terms

$$[D_tu_eD_tu_e]^n = (u'_e(t_n))^2 + \frac{1}{12}u_e(t_n)u'''_e(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4).$$

With

$$m[D_tD_tu_e]^n = mu''_e(t_n) + \frac{m}{12}u''''_e(t_n)\Delta t^2 + \mathcal{O}(\Delta t^4),$$

and using the differential equation on the form $mu'' + \beta(u')^2 + s(u) = F$, we end up with

$$R^n = (\frac{m}{12}u''''_e(t_n) + \frac{\beta}{12}u_e(t_n)u'''_e(t_n))\Delta t^2 + \mathcal{O}(\Delta t^4).$$

This result demonstrates that we have second-order accuracy also with quadratic damping. The key elements that lead to the second-order accuracy is that the difference approximations are $\mathcal{O}(\Delta t^2)$ *and* the geometric mean approximation is also of $\mathcal{O}(\Delta t^2)$.

.4 The general model formulated as first-order ODEs

The second-order model (59) can be formulated as a first-order system,

$$u' = v, \tag{62}$$
$$v' = \frac{1}{m}\left(F(t) - \beta|v|v - s(u)\right). \tag{63}$$

The system (62)-(62) can be solved either by a forward-backward scheme or a centered scheme on a staggered mesh.

The forward-backward scheme. The discretization is based on the stepping (62) forward in time and then using a backward difference in (6 the recently computed (and therefore known) u:

$$[D_t^+u = v]^n,$$
$$[D_t^-v = \frac{1}{m}(F(t) - \beta|v|v - s(u))]^{n+1}.$$

The term $|v|v$ gives rise to a nonlinearity $|v^{n+1}|v^{n+1}$, which can be linea $|v^n|v^{n+1}$:

$$[D_t^+u = v]^n,$$
$$[D_t^-v]^{n+1} = \frac{1}{m}(F(t_{n+1}) - \beta|v^n|v^{n+1} - s(u^{n+1})).$$

Each ODE will have a truncation error when inserting the exact solu and v_e in (64)-(65):

$$[D_t^+u_e = v_e + R_u]^n,$$
$$[D_t^-v_e]^{n+1} = \frac{1}{m}(F(t_{n+1}) - \beta|v_e(t_n)|v_e(t_{n+1}) - s(u_e(t_{n+1}))) + R_v^{n+1}$$

Application of (11)-(12) and (9)-(10) in (68) and (69), respectively, give

$$u'_e(t_n) + \frac{1}{2}u''_e(t_n)\Delta t + \mathcal{O}(\Delta t^2) = v_e(t_n) + R_u^n,$$
$$v'_e(t_{n+1}) - \frac{1}{2}v''_e(t_{n+1})\Delta t + \mathcal{O}(\Delta t^2) = \frac{1}{m}(F(t_{n+1}) - \beta|v_e(t_n)|v_e(t_{n+})$$
$$s(u_e(t_{n+1})) + R_v^n.$$

Since $u'_e = v_e$, (70) gives

$$R_u^n = \frac{1}{2}u''_e(t_n)\Delta t + \mathcal{O}(\Delta t^2).$$

In (71) we can collect the terms that constitute the ODE, but the dampi has the wrong form. Let us drop the absolute value in the damping t simplicity. Adding a substracting the right form $v^{n+1}v^{n+1}$ helps:

$$v'_e(t_{n+1}) - \frac{1}{m}(F(t_{n+1}) - \beta v_e(t_{n+1})v_e(t_{n+1}) + s(u_e(t_{n+1})) +$$
$$(\beta v_e(t_n)v_e(t_{n+1}) - \beta v_e(t_{n+1})v_e(t_{n+1}))),$$

which reduces to

$$\frac{\beta}{m}v_e(t_{n+1}(v_e(t_n) - v_e(t_{n+1})) = \frac{\beta}{m}v_e(t_{n+1}[D_t^- v_e]^{n+1}\Delta t$$
$$= \frac{\beta}{m}v_e(t_{n+1}(v_e'(t_{n+1})\Delta t + -\frac{1}{2}v_e'''(t_{n+1})\Delta t + \mathcal{O}(\Delta t^3)) .$$

We end with R_u^n and R_v^{n+1} as $\mathcal{O}(\Delta t)$, simply because all the building blocks in the schemes (the forward and backward differences and the linearization trick) are only first-order accurate. However, this analysis is misleading: the building blocks play together in a way that makes the scheme second-order accurate. This is shown by considering an alternative, yet equivalent, formulation of the above scheme.

A centered scheme on a staggered mesh. We now introduce a staggered mesh where we seek u at mesh points t_n and v at points $t_{n+\frac{1}{2}}$ in between the u points. The staggered mesh makes it easy to formulate centered differences in the system (62)-(62):

$$[D_t u = v]^{n-\frac{1}{2}}, \tag{72}$$

$$[D_t v = \frac{1}{m}(F(t) - \beta|v|v - s(u))]^n . \tag{73}$$

The term $|v^n|v^n$ causes trouble since v^n is not computed, only $v^{n-\frac{1}{2}}$ and $v^{n+\frac{1}{2}}$. Using geometric mean, we can express $|v^n|v^n$ in terms of known quantities: $v^n|v^n \approx |v^{n-\frac{1}{2}}|v^{n+\frac{1}{2}}$. We then have

$$[D_t u]^{n-\frac{1}{2}} = v^{n-\frac{1}{2}}, \tag{74}$$

$$[D_t v]^n = \frac{1}{m}(F(t_n) - \beta|v^{n-\frac{1}{2}}|v^{n+\frac{1}{2}} - s(u^n)) . \tag{75}$$

The truncation error in each equation fulfills

$$[D_t u_e]^{n-\frac{1}{2}} = v_e(t_{n-\frac{1}{2}}) + R_u^{n-\frac{1}{2}},$$

$$[D_t v_e]^n = \frac{1}{m}(F(t_n) - \beta|v_e(t_{n-\frac{1}{2}})|v_e(t_{n+\frac{1}{2}}) - s(u^n)) + R_v^n .$$

The truncation error of the centered differences is given by (5)-(6), and the geometric mean approximation analysis can be taken from (23)-(24). These results lead to

$$u_e'(t_{n-\frac{1}{2}}) + \frac{1}{24}u_e'''(t_{n-\frac{1}{2}})\Delta t^2 + \mathcal{O}(\Delta t^4) = v_e(t_{n-\frac{1}{2}}) + R_u^{n-\frac{1}{2}},$$

and

$$v_e'(t_n) = \frac{1}{m}(F(t_n) - \beta|v_e(t_n)|v_e(t_n) + \mathcal{O}(\Delta t^2) - s(u^n)) + R_v^n .$$

The ODEs fulfilled by u_e and v_e are evident in these equations, and we second-order accuracy for the truncation error in both equations:

$$R_u^{n-\frac{1}{2}} = \mathcal{O}(\Delta t^2), \quad R_v^n = \mathcal{O}(\Delta t^2) .$$

Comparing (74)-(75) with (66)-(67), we can hopefully realize tha schemes are equivalent (which becomes clear when we implement bot) obvious advantage with the staggered mesh approach is that we can all use second-order accurate building blocks and in this way concince o that the resulting scheme has an error of $\mathcal{O}(\Delta t^2)$.

5 Truncation errors in wave equations

5.1 Linear wave equation in 1D

The standard, linear wave equation in 1D for a function $u(x,t)$ reads

$$\frac{\partial^2 u}{\partial t^2} = c^2 \frac{\partial^2 u}{\partial x^2} + f(x,t), \quad x \in (0,L), \ t \in (0,T],$$

where c is the constant wave velocity of the physical medium $[0,L]$. The e can also be more compactly written as

$$u_{tt} = c^2 u_{xx} + f, \quad x \in (0,L), \ t \in (0,T],$$

Centered, second-order finite differences are a natural choice for discreti derivatives, leading to

$$[D_t D_t u = c^2 D_x D_x u + f]_i^n .$$

Inserting the exact solution $u_e(x,t)$ in (78) makes this function fu equation if we add the term R:

$$[D_t D_t u_e = c^2 D_x D_x u_e + f + R]_i^n$$

Our purpose is to calculate the truncation error R. From (17)-(18) that

$$[D_t D_t u_e]_i^n = u_{e,tt}(x_i,t_n) + \frac{1}{12}u_{e,tttt}(x_i,t_n)\Delta t^2 + \mathcal{O}(\Delta t^4),$$

when we use a notation taking into account that u_e is a function of two v and that derivatives must be partial derivatives. The notation $u_{e,tt}$ $\partial^2 u_e/\partial t^2$.

The same formula may also be applied to the x-derivative term:

$$[D_x D_x u_e]_i^n = u_{e,xx}(x_i,t_n) + \frac{1}{12}u_{e,xxxx}(x_i,t_n)\Delta x^2 + \mathcal{O}(\Delta x^4),$$

Equation (81) now becomes

$$u_{e,tt} + \frac{1}{12}u_{e,tttt}(x_i,t_n)\Delta t^2 = c^2 u_{e,xx} + c^2 \frac{1}{12}u_{e,xxxx}(x_i,t_n)\Delta x^2 + f(x_i,t_n) +$$
$$\mathcal{O}(\Delta t^4, \Delta x^4) + R_i^n \,.$$

Because u_e fulfills the partial differential equation (PDE) (77), the first, third, and fifth terms cancel out, and we are left with

$$R_i^n = \frac{1}{12}u_{e,tttt}(x_i,t_n)\Delta t^2 - c^2 \frac{1}{12}u_{e,xxxx}(x_i,t_n)\Delta x^2 + \mathcal{O}(\Delta t^4, \Delta x^4), \quad (80)$$

showing that the scheme (78) is of second order in the time and space mesh spacing.

.2   Finding correction terms

Can we add correction terms to the PDE and increase the order of R_i^n in (80)? The starting point is

$$[D_t D_t u_e = c^2 D_x D_x u_e + f + C + R]_i^n \quad (81)$$

From the previous analysis we simply get (80) again, but now with C:

$$R_i^n + C_i^n = \frac{1}{12}u_{e,tttt}(x_i,t_n)\Delta t^2 - c^2 \frac{1}{12}u_{e,xxxx}(x_i,t_n)\Delta x^2 + \mathcal{O}(\Delta t^4, \Delta x^4) \,. \quad (82)$$

The idea is to let C_i^n cancel the Δt^2 and Δx^2 terms to make $R_i^n = \mathcal{O}(\Delta t^4, \Delta x^4)$:

$$C_i^n = \frac{1}{12}u_{e,tttt}(x_i,t_n)\Delta t^2 - c^2 \frac{1}{12}u_{e,xxxx}(x_i,t_n)\Delta x^2 \,.$$

Essentially, it means that we add a new term

$$C = \frac{1}{12}\left(u_{tttt}\Delta t^2 - c^2 u_{xxxx}\Delta x^2\right),$$

to the right-hand side of the PDE. We must either discretize these 4th-order derivatives directly or rewrite them in terms of lower-order derivatives with the aid of the PDE. The latter approach is more feasible. From the PDE we have that

$$\frac{\partial^2}{\partial t^2} = c^2 \frac{\partial^2}{\partial x^2},$$

so

$$u_{tttt} = c^2 u_{xxtt}, \quad u_{xxxx} = c^{-2} u_{ttxx} \,.$$

Assuming u is smooth enough that $u_{xxtt} = u_{ttxx}$, these relations lead to

$$C = \frac{1}{12}((c^2\Delta t^2 - \Delta x^2)u_{xx})_{tt} \,.$$

31

A natural discretization is

$$C_i^n = \frac{1}{12}((c^2\Delta t^2 - \Delta x^2)[D_x D_x D_t D_t u]_i^n \,.$$

Writing out $[D_x D_x D_t D_t u]_i^n$ as $[D_x D_x (D_t D_t u)]_i^n$ gives

$$\frac{1}{\Delta t^2}\left(\frac{u_{i+1}^{n+1} - 2u_{i+1}^n + u_{i+1}^{n-1}}{\Delta x^2} - 2\right.$$
$$\frac{u_i^{n+1} - 2u_i^n + u_i^{n-1}}{\Delta x^2} + \left.\frac{u_{i-1}^{n+1} - 2u_{i-1}^n + u_{i-1}^{n-1}}{\Delta x^2}\right)$$

Now the unknown values u_{i+1}^{n+1}, u_i^{n+1}, and u_{i-1}^{n+1} are *coupled*, and we mu a tridiagonal system to find them. This is in principle straightforward results in an implicit finite difference schemes, while we had a convenient scheme without the correction terms.

5.3   Extension to variable coefficients

Now we address the variable coefficient version of the linear 1D wave e

$$\frac{\partial^2 u}{\partial t^2} = \frac{\partial}{\partial x}\left(\lambda(x)\frac{\partial u}{\partial x}\right),$$

or written more compactly as

$$u_{tt} = (\lambda u_x)_x \,.$$

The discrete counterpart to this equation, using arithmetic mean for centered differences, reads

$$[D_t D_t u = D_x \overline{\lambda}^x D_x u]_i^n \,.$$

The truncation error is the residual R in the equation

$$[D_t D_t u_e = D_x \overline{\lambda}^x D_x u_e + R]_i^n \,.$$

The difficulty in the present is how to compute the truncation error of t $[D_x \overline{\lambda}^x D_x u_e]_i^n$.

We start by writing out the outer operator:

$$[D_x \overline{\lambda}^x D_x u_e]_i^n = \frac{1}{\Delta x}\left([\overline{\lambda}^x D_x u_e]_{i+\frac{1}{2}}^n - [\overline{\lambda}^x D_x u_e]_{i-\frac{1}{2}}^n\right) \,.$$

With the aid of (5)-(6) and (21)-(22) we have

32

$$[D_x u_\mathrm{e}]_{i+\frac{1}{2}}^n = u_{\mathrm{e},x}(x_{i+\frac{1}{2}}, t_n) + \frac{1}{24} u_{\mathrm{e},xxx}(x_{i+\frac{1}{2}}, t_n)\Delta x^2 + \mathcal{O}(\Delta x^4),$$

$$[\overline{\lambda}^x]_{i+\frac{1}{2}} = \lambda(x_{i+\frac{1}{2}}) + \frac{1}{8}\lambda''(x_{i+\frac{1}{2}})\Delta x^2 + \mathcal{O}(\Delta x^4),$$

$$[\overline{\lambda}^x D_x u_\mathrm{e}]_{i+\frac{1}{2}}^n = (\lambda(x_{i+\frac{1}{2}}) + \frac{1}{8}\lambda''(x_{i+\frac{1}{2}})\Delta x^2 + \mathcal{O}(\Delta x^4))\times$$

$$(u_{\mathrm{e},x}(x_{i+\frac{1}{2}}, t_n) + \frac{1}{24}u_{\mathrm{e},xxx}(x_{i+\frac{1}{2}}, t_n)\Delta x^2 + \mathcal{O}(\Delta x^4))$$

$$= \lambda(x_{i+\frac{1}{2}})u_{\mathrm{e},x}(x_{i+\frac{1}{2}}, t_n) + \lambda(x_{i+\frac{1}{2}})\frac{1}{24}u_{\mathrm{e},xxx}(x_{i+\frac{1}{2}}, t_n)\Delta x^2 +$$

$$u_{\mathrm{e},x}(x_{i+\frac{1}{2}})\frac{1}{8}\lambda''(x_{i+\frac{1}{2}})\Delta x^2 + \mathcal{O}(\Delta x^4)$$

$$= [\lambda u_{\mathrm{e},x}]_{i+\frac{1}{2}}^n + G_{i+\frac{1}{2}}^n \Delta x^2 + \mathcal{O}(\Delta x^4),$$

here we have introduced the short form

$$G_{i+\frac{1}{2}}^n = (\frac{1}{24}u_{\mathrm{e},xxx}(x_{i+\frac{1}{2}}, t_n)\lambda((x_{i+\frac{1}{2}}) + u_{\mathrm{e},x}(x_{i+\frac{1}{2}}, t_n)\frac{1}{8}\lambda''(x_{i+\frac{1}{2}}))\Delta x^2\,.$$

imilarly, we find that

$$[\overline{\lambda}^x D_x u_\mathrm{e}]_{i-\frac{1}{2}}^n = [\lambda u_{\mathrm{e},x}]_{i-\frac{1}{2}}^n + G_{i-\frac{1}{2}}^n \Delta x^2 + \mathcal{O}(\Delta x^4)\,.$$

serting these expressions in the outer operator (86) results in

$$_x\overline{\lambda}^x D_x u_\mathrm{e}]_i^n = \frac{1}{\Delta x}([\overline{\lambda}^x D_x u_\mathrm{e}]_{i+\frac{1}{2}}^n - [\overline{\lambda}^x D_x u_\mathrm{e}]_{i-\frac{1}{2}}^n)$$

$$= \frac{1}{\Delta x}([\lambda u_{\mathrm{e},x}]_{i+\frac{1}{2}}^n + G_{i+\frac{1}{2}}^n \Delta x^2 - [\lambda u_{\mathrm{e},x}]_{i-\frac{1}{2}}^n - G_{i-\frac{1}{2}}^n \Delta x^2 + \mathcal{O}(\Delta x^4))$$

$$= [D_x \lambda u_{\mathrm{e},x}]_i^n + [D_x G]_i^n \Delta x^2 + \mathcal{O}(\Delta x^4)\,.$$

he reason for $\mathcal{O}(\Delta x^4)$ in the remainder is that there are coefficients in front f this term, say $H\Delta x^4$, and the subtraction and division by Δx results in $_x H]_i^n \Delta x^4$.

We can now use (5)-(6) to express the D_x operator in $[D_x \lambda u_{\mathrm{e},x}]_i^n$ as a erivative and a truncation error:

$$[D_x \lambda u_{\mathrm{e},x}]_i^n = \frac{\partial}{\partial x}\lambda(x_i)u_{\mathrm{e},x}(x_i, t_n) + \frac{1}{24}(\lambda u_{\mathrm{e},x})_{xxx}(x_i, t_n)\Delta x^2 + \mathcal{O}(\Delta x^4)\,.$$

xpressions like $[D_x G]_i^n \Delta x^2$ can be treated in an identical way,

$$[D_x G]_i^n \Delta x^2 = G_x(x_i, t_n)\Delta x^2 + \frac{1}{24}G_{xxx}(x_i, t_n)\Delta x^4 + \mathcal{O}(\Delta x^4)\,.$$

There will be a number of terms with the Δx^2 factor. We lump th into $\mathcal{O}(\Delta x^2)$. The result of the truncation error analysis of the spatial de is therefore summarized as

$$[D_x\overline{\lambda}^x D_x u_\mathrm{e}]_i^n = \frac{\partial}{\partial x}\lambda(x_i)u_{\mathrm{e},x}(x_i, t_n) + \mathcal{O}(\Delta x^2)\,.$$

After having treated the $[D_t D_t u_\mathrm{e}]_i^n$ term as well, we achieve

$$R_i^n = \mathcal{O}(\Delta x^2) + \frac{1}{12}u_{\mathrm{e},tttt}(x_i, t_n)\Delta t^2\,.$$

The main conclusion is that the scheme is of second-order in time an also in this variable coefficient case. The key ingredients for second or the centered differences and the arithmetic mean for λ: all those buildin feature second-order accuracy.

5.4 1D wave equation on a staggered mesh

5.5 Linear wave equation in 2D/3D

The two-dimensional extension of (76) takes the form

$$\frac{\partial^2 u}{\partial t^2} = c^2\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right) + f(x, y, t), \quad (x, y) \in (0, L) \times (0, H),\ t \in (0,\ ]$$

where now $c(x, y)$ is the constant wave velocity of the physical medium $[0, H]$. In the compact notation, the PDE (87) can be written

$$u_{tt} = c^2(u_{xx} + u_{yy}) + f(x, y, t), \quad (x, y) \in (0, L) \times (0, H),\ t \in (0, T],$$

in 2D, while the 3D version reads

$$u_{tt} = c^2(u_{xx} + u_{yy} + u_{zz}) + f(x, y, z, t),$$

for $(x, y, z) \in (0, L) \times (0, H) \times (0, B)$ and $t \in (0, T]$.

Approximating the second-order derivatives by the standard formu (18) yields the scheme

$$[D_t D_t u = c^2(D_x D_x u + D_y D_y u) + f]_{i,j,k}^n\,.$$

The truncation error is found from

$$[D_t D_t u_\mathrm{e} = c^2(D_x D_x u_\mathrm{e} + D_y D_y u_\mathrm{e}) + f + R]^n\,.$$

The calculations from the 1D case can be repeated to the terms in the directions. Collecting terms that fulfill the PDE, we end up with

$$R_{i,j,k}^n = [\frac{1}{12}u_{\mathrm{e},tttt}\Delta t^2 - c^2\frac{1}{12}\left(u_{\mathrm{e},xxxx}\Delta x^2 + u_{\mathrm{e},yyyy}\Delta x^2 + u_{\mathrm{e},zzzz}\Delta z^2\right)$$

$$\mathcal{O}(\Delta t^4, \Delta x^4, \Delta y^4, \Delta z^4)\,.$$

6 Truncation errors in diffusion equations

6.1 Linear diffusion equation in 1D

The standard, linear, 1D diffusion equation takes the form

$$\frac{\partial u}{\partial t} = \alpha \frac{\partial^2 u}{\partial x^2} + f(x,t), \quad x \in (0,L), \ t \in (0,T], \tag{93}$$

where $\alpha > 0$ is the constant diffusion coefficient. A more compact form of the diffusion equation is $u_t = \alpha u_{xx} + f$.

The spatial derivative in the diffusion equation, $\alpha u_x x$, is commonly discretized as $[D_x D_x u]_i^n$. The time-derivative, however, can be treated by a variety of methods.

The Forward Euler scheme in time. Let us start with the simple Forward Euler scheme:

$$[D_t^+ u = \alpha D_x D_x u + f]^n .$$

The truncation error arises as the residual R when inserting the exact solution u_e in the discrete equations:

$$[D_t^+ u_e = \alpha D_x D_x u_e + f + R]_i^n .$$

Now, using (11)-(12) and (17)-(18), we can transform the difference operators to derivatives:

$$u_{e,t}(x_i,t_n) + \frac{1}{2}u_{e,tt}(t_n)\Delta t + \mathcal{O}(\Delta t^2) = \alpha u_{e,xx}(x_i,t_n) +$$
$$\frac{\alpha}{12}u_{e,xxxx}(x_i,t_n)\Delta x^2 + \mathcal{O}(\Delta x^4) + f(x_i,t_n) + R_i^n .$$

The terms $u_{e,t}(x_i,t_n) - \alpha u_{e,xx}(x_i,t_n) - f(x_i,t_n)$ vansih because u_e solves the PDE. The truncation error then becomes

$$R_i^n = \frac{1}{2}u_{e,tt}(t_n)\Delta t + \mathcal{O}(\Delta t^2) - \frac{\alpha}{12}u_{e,xxxx}(x_i,t_n)\Delta x^2 + \mathcal{O}(\Delta x^4) .$$

The Crank-Nicolson scheme in time. The Crank-Nicolson method consists of using a centered difference for u_t and an arithmetic average of the $u_x x$ term:

$$[D_t u]_i^{n+\frac{1}{2}} = \alpha \frac{1}{2}([D_x D_x u]_i^n + [D_x D_x u]_i^{n+1} + f_i^{n+\frac{1}{2}} .$$

The equation for the truncation error is

$$[D_t u_e]_i^{n+\frac{1}{2}} = \alpha \frac{1}{2}([D_x D_x u_e]_i^n + [D_x D_x u_e]_i^{n+1}) + f_i^{n+\frac{1}{2}} + R_i^{n+\frac{1}{2}} .$$

To find the truncation error, we start by expressing the arithmetic average in terms of values at time $t_{n+\frac{1}{2}}$. According to (21)-(22),

$$\frac{1}{2}([D_x D_x u_e]_i^n + [D_x D_x u_e]_i^{n+1}) = [D_x D_x u_e]_i^{n+\frac{1}{2}} + \frac{1}{8}[D_x D_x u_{e,tt}]_i^{n+\frac{1}{2}}\Delta t^2 + \mathcal{O}($$

With (17)-(18) we can express the difference operator $D_x D_x u$ in ter derivative:

$$[D_x D_x u_e]_i^{n+\frac{1}{2}} = u_{e,xx}(x_i,t_{n+\frac{1}{2}}) + \frac{1}{12}u_{e,xxxx}(x_i,t_{n+\frac{1}{2}})\Delta x^2 + \mathcal{O}(\Delta x)$$

The error term from the arithmetic mean is similarly expanded,

$$\frac{1}{8}[D_x D_x u_{e,tt}]_i^{n+\frac{1}{2}}\Delta t^2 = \frac{1}{8}u_{e,ttxx}(x_i,t_{n+\frac{1}{2}})\Delta t^2 + \mathcal{O}(\Delta t^2 \Delta x^2)$$

The time derivative is analyzed using (5)-(6):

$$[D_t u]_i^{n+\frac{1}{2}} = u_{e,t}(x_i,t_{n+\frac{1}{2}}) + \frac{1}{24}u_{e,ttt}(x_i,t_{n+\frac{1}{2}})\Delta t^2 + \mathcal{O}(\Delta t^4) .$$

Summing up all the contributions and notifying that

$$u_{e,t}(x_i,t_{n+\frac{1}{2}}) = \alpha u_{e,xx}(x_i,t_{n+\frac{1}{2}}) + f(x_i,t_{n+\frac{1}{2}}),$$

the truncation error is given by

$$R_i^{n+\frac{1}{2}} = \frac{1}{8}u_{e,xx}(x_i,t_{n+\frac{1}{2}})\Delta t^2 + \frac{1}{12}u_{e,xxxx}(x_i,t_{n+\frac{1}{2}})\Delta x^2 +$$
$$\frac{1}{24}u_{e,ttt}(x_i,t_{n+\frac{1}{2}})\Delta t^2 + + \mathcal{O}(\Delta x^4) + \mathcal{O}(\Delta t^4) + \mathcal{O}(\Delta t^2 \Delta x^2)$$

6.3 A nonlinear diffusion equation in 2D

7 Exercises

Exercise 1: Truncation error of a weighted mean

Derive the truncation error of the weighted mean in (19)-(20).

Hint. Expand u_e^{n+1} and u_e^n around $t_{n+\theta}$.
Filename: `trunc_weighted_mean.pdf`.

Exercise 2: Simulate the error of a weighted mean

We consider the weighted mean

$$u_e(t_n) \approx \theta u_e^{n+1} + (1-\theta)u_e^n .$$

Choose some specific function for $u_e(t)$ and compute the error in this appr tion for a sequence of decreasing $\Delta t = t_{n+1} - t_n$ and for $\theta = 0, 0.25, 0.5$ Assuming that the error equals $C\Delta t^r$, for some constants C and r, comp the two smallest Δt values for each choice of θ and compare with the tru error (19)-(20). Filename: `trunc_theta_avg.py`.

Exercise 3: Verify a truncation error formula

Set up a numerical experiment as explained in Section 3.5 for verifying the formulas (15)-(16). Filename: `trunc_backward_2level.py`.

Exercise 4: Truncation error of the Backward Euler scheme

Derive the truncation error of the Backward Euler scheme for the decay ODE $u' = -au$ with constant a. Extend the analysis to cover the variable-coefficient case $u' = -a(t)u + b(t)$. Filename: `trunc_decay_BE.py`.

Exercise 5: Empirical estimation of truncation errors

Use the ideas and tools from Section 3.5 to estimate the rate of the truncation error of the Backward Euler and Crank-Nicolson schemes applied to the exponential decay model $u' = -au$, $u(0) = I$.

Hint. In the Backward Euler scheme, the truncation error can be estimated at mesh points $n = 1, \ldots, N$, while the truncation error must be estimated at midpoints $t_{n+\frac{1}{2}}$, $n = 0, \ldots, N - 1$ for the Crank-Nicolson scheme. The `truncation_error(dt, N)` function to be supplied to the `estimate` function needs to carefully implement these details and return the right `t` array such that `t[i]` is the time point corresponding to the quantities `R[i]` and `R_a[i]`.
Filename: `trunc_decay_BNCN.py`.

Exercise 6: Correction term for a Backward Euler scheme

Consider the model $u' = -au$, $u(0) = I$. Use the ideas of Section 3.6 to add a correction term to the ODE such that the Backward Euler scheme applied to the perturbed ODE problem is of second order in Δt. Find the amplification factor.
Filename: `trunc_decay_BE_corr.pdf`.

Exercise 7: Verify the effect of correction terms

The program `decay_convrate.py`[4] solves $u' = -au$, $u(0) = I$, by the θ-rule and computes convergence rates. Copy this file and adjust a in the `solver` function such that it incorporates correction terms. Run the program to verify that the error from the Forward and Backward Euler schemes with perturbed a is $\mathcal{O}(\Delta t^2)$, while the error arising from the Crank-Nicolson scheme with perturbed is $\mathcal{O}(\Delta t^4)$. Filename: `trunc_decay_corr_verify.py`.

Exercise 8: Truncation error of the Crank-Nicolson scheme

The variable-coefficient ODE $u' = -a(t)u + b(t)$ can be discretized in two different ways by the Crank-Nicolson scheme, depending on whether we use averages for a and b or compute them at the midpoint $t_{n+\frac{1}{2}}$:

$$[D_t u = -a\overline{u}^t + b]^{n+\frac{1}{2}}, \tag{94}$$

$$[D_t u = \overline{-au + b}^t]^{n+\frac{1}{2}}. \tag{95}$$

Compute the truncation error in both cases. Filename: `trunc_decay_CN_vc.pdf`.

[4]`http://tinyurl.com/jvzzcfn/decay/decay_convrate.py`

Exercise 9: Truncation error of $u' = f(u, t)$

Consider the general nonlinear first-order scalar ODE

$$u'(t) = f(u(t), t).$$

Show that the truncation error in the Forward Euler scheme,

$$[D_t^+ u = f(u, t)]^n,$$

and in the Backward Euler scheme,

$$[D_t^- u = f(u, t)]^n,$$

both are of first order, regardless of what f is.
Showing the order of the truncation error in the Crank-Nicolson scheme

$$[D_t u = f(u, t)]^{n+\frac{1}{2}},$$

is somewhat more involved: Taylor expand u_e^n, u_e^{n+1}, $f(u_e^n, t_n)$, and $f(u_e^{n}$ around $t_{n+\frac{1}{2}}$, and use that

$$\frac{df}{dt} = \frac{\partial f}{\partial u}u' + \frac{\partial f}{\partial t}.$$

Check that the derived truncation error is consistent with previous res the case $f(u, t) = -au$. Filename: `trunc_nonlinear_ODE.pdf`.

Exercise 10: Truncation error of $[D_t D_t u]^n$

Derive the truncation error of the finite difference approximation (17) the second-order derivative. Filename: `trunc_d2u.pdf`.

Exercise 11: Investigate the impact of approximating

Section 4.1 describes two ways of discretizing the initial conditon $u'(0)$ a vibration model $u'' + \omega^2 u = 0$: a centered difference $[D_{2t}u = V]^0$ or a difference $[D_t^+ u = V]^0$. The program `vib_undamped.py`[5] solves $u'' +$ with $[D_{2t}u = 0]^0$ and features a function `convergence_rates` for compu order of the error in the numerical solution. Modify this program such applies the forward difference $[D_t^+ u = 0]^0$ and report how this simpler an convenient approximation impacts the overall convergence rate of the Filename: `trunc_vib_ic_fw.py`.

Exercise 12: Investigate the accuracy of a simplified s

Consider the ODE

$$mu'' + \beta|u'|u' + s(u) = F(t).$$

[5]`http://tinyurl.com/jvzzcfn/vib/vib_undamped.py`

he term $|u'|u'$ quickly gives rise to nonlinearities and complicates the scheme. Why not simply apply a backward difference to this term such that it only involves known values? That is, we propose to solve

$$[mD_tD_tu + \beta|D_t^-u|D_t^-u + s(u) = F]^n.$$

drop the absolute value for simplicity and find the truncation error of the scheme. erform numerical experiments with the scheme and compared with the one ased on centered differences. Can you illustrate the accuracy loss visually in real omputations, or is the asymptotic analysis here mainly of theoretical interest? ilename: `trunc_vib_bw_damping.pdf`.
